USE OF WEANING FOODS (BEIKOST) IN AN INDUSTRIALIZED SOCIETY

Socio economic and Psychological Aspects

EVA MARI KÖHLER LENNART KÖHLER and BERTIL LINDQUIST

From the Department of Paediatrics University Hospital Lund Sweden

ABSTRACT Kohler E M Kohler L and Lindquist B (Department of Paediatrics University Hospital Lund Sweden) Use of Weaning Foods (Beikost) in an industrialized society Socio-economic and psychological aspects Acta Paediatr Scand 66 665 1977.— An interview was performed among mothers of 466 children aged 6–18 months in order to elucidate which factors influence the parents choice of industrially produced or home made foods when feeding their infants with Beikost The use of canned foods was more popular among mothers of very young children the families own table food being considered as nutritionally not adequate and also less convenient The home-cookers on the other hand were convinced that industrially prepared Beikost was not necessary from nutritional taste or economical aspects Feeding problems occurred in about 15% of all families irrespective of feeding practices Social and economic factors like education working and money spent on food seemed to influence the families choice of food for the children to a very small extent implying that the way of feeding children had no deeper impact on their standard of living Instead the mother s own activities interest knowledge and ideas of how to feed children were decisive for her choice the home cookers were more interested in household work like shopping baking and cooking and these activities did not exhaust them as much as they did the jar buyers Information from the food industries was the most important source for the parents knowledge about nutrition and feeding of babies irrespective of their feeding practices After knowledge due to experience from older children the Child Health Centres were the third most appreciated source of information It is therefore most important that the baby food industries give information of high quality and that they follow certain ethical principles preferably formulated by paediatricians acting as medical consultants to the industry However the primary responsibility for information to parents about baby food falls on the country s health authorities Considering the apprehension of feeding management often revealed by the mothers and also the relatively high frequency of feeding problems reported it seems wise to educate and support the Child Health Centres towards a more active participation on nutritional matters

KEY WORDS Weaning foods feeding practices Beikost baby food industry

The consumption of industrially produced baby food in Sweden has increased dramatically during the last decades In 1975 the average Swedish infant consumed about 70 litres of starting infant formulas (used from birth up to 4–5 months of age) and about 600 jars of solid and semisolid baby food (so called Beikost)[1] (12) (Fig 1)

From every point of view it is obvious that breastfeeding is the best feeding system for babies and this fact is no doubt accepted also by the baby food industries today It is also generally and officially accepted that home made infant formulas cannot assure the infant the same adequate nutrition as can the industrially produced formulas (3)

[1] In this calculation it is assumed that Beikost is entirely consumed by infants This is however not true to some extent it is also consumed by toddlers and by older persons

ABSTRACT Kohler E M Kohler L and Lindquist B (Department of Paediatrics University Hospital Lund Sweden) Use of Weaning Foods (Beikost) in an industrialized society Socio-economic and psychological aspects Acta Paediatr Scand 66 665 1977 — An interview was performed among mothers of 466 children aged 6–18 months in order to elucidate which factors influence the parents choice of industrially produced or home made foods when feeding their infants with Beikost The use of canned foods was more popular among mothers of very young children the families own table food being considered as nutritionally not adequate and also less convenient The home cookers on the other hand were convinced that industrially prepared Beikost was not necessary from nutritional taste or economical aspects Feeding problems occurred in about 15% of all families irrespective of feeding practices Social and economic factors like education working and money spent on food seemed to influence the families choice of food for the children to a very small extent implying that the way of feeding children had no deeper impact on their standard of living Instead the mother s own activities interest knowledge and ideas of how to feed children were decisive for her choice the home-cookers were more interested in house hold work like shopping baking and cooking and these activities did not exhaust them as much as they did the jar buyers Information from the food industries was the most important source for the parents knowledge about nutrition and feeding of babies irrespective of their feeding practices After knowledge due to experience from older children the Child Health Centres were the third most appreciated source of information It is therefore most important that the baby food industries give information of high quality and that they follow certain ethical principles preferably formulated by paediatricians acting as medical consultants to the industry However the primary responsibility for information to parents about baby food falls on the country s health authorities Considering the apprehension of feeding management often revealed by the mothers and also the relatively high frequency of feeding problems reported it seems wise to educate and support the Child Health Centres towards a more active participation on nutritional matters

KEY WORDS Weaning foods feeding practices Beikost baby food industry

The consumption of industrially produced baby food in Sweden has increased dramatically during the last decades In 1975 the average Swedish infant consumed about 70 litres of starting infant formulas (used from birth up to 4–5 months of age) and about 600 jars of solid and semisolid baby food (so called Beikost)[1] (12) (Fig 1)

From every point of view it is obvious that breastfeeding is the best feeding system for babies and this fact is no doubt accepted also by the baby food industries today It is also generally and officially accepted that home made infant formulas cannot assure the infant the same adequate nutrition as can the industrially produced formulas (3)

---

[1] In this calculation it is assumed that Beikost is entirely consumed by infants This is however not true to some extent it is also consumed by toddlers and by older persons

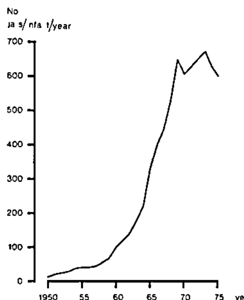

Fig 1 Consumption of baby food in jars in Sweden expressed as number of jars per infant and year (It is assumed that all consumption is made by infants the consumption by others e g older people is disregarded)

However the wisdom of giving industrially produced Beikost has been questioned It has been argued that these products contain poisons (e g nitrates biocides) that they contain unnecessary additives (colours etc), that vital ingredients e g vitamins are destroyed during the processing operations and furthermore that the taste and consistency of the food are too weak and soft to teach the children the sensation of real food in the mouth

The industry scientists and the nutritional physiologists have refuted these arguments by stating that the industries careful selection of the best raw products as well as the rigorous control and surveillance of the production lines are in fact the best guarantee for high quality and poisonfree baby food They also mean that the selection possibilities between various foods and the convenience of having a product in a jar ready when the child is hungry makes life much easier for the parents and for the child

Exactly which motives lie behind the parents selection of way of feeding are not known which people prefer to use canned baby food—and ctors influence their choice—in comparison to those preferring home made food? How important is the professional advice from the Child Health Centres in establishing the children s eating habits?

In order to elucidate these and other factors of socio economic and psychological nature which might influence the parents way of feeding their infants and toodlers with Beikost a study was performed interviewing mothers in a health district in Southern Sweden

MATERIAL

In the district consisting of one industrial town surrounded by small villages and countryside all 624 children aged 6–18 months were selected from the county population register Children with parents who did not speak or understand Swedish were excluded from the study (36 families) Another 39 families had moved from the area Of the remaining 549 families 83 (15 1%) had no time or refused to cooperate Thus 466 children 256 in the town and 210 in the villages and in the countryside participated in the study The age of the children were as follows 74 6–10 months 65 10–12 months and 327 12–18 months of age

METHODS

After arranging an appointment a trained interviewer visited the families homes and performed the interview which consisted of about 75 questions and took about 1 hour The interviewer was very well received and most of the mothers seized the opportunity to talk lengthy and *freely to someone who was genuinely interested in their* babies and their everyday small problems

RESULTS

Feeding practices

The frequency of breastfeeding was somewhat higher than in Sweden as a whole (Fig 2) When breastfeeding ceased all children were given industrially produced infant formulas from a bottle

The introduction of Beikost in Sweden is recommended at 3–4 months of age (3) In the present material it occurred in 73% at this age and at the age of about 6 months one meal of breastmilk/formula was replaced by Beikost in about two thirds of the children according to general recommendations (3) By then the

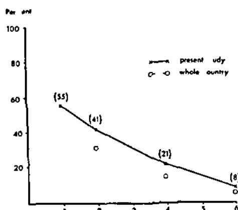

Fig 2 Totally breastfed children Figures for whole country represent official statistics in Sweden for 1970

majority preferred to give industrially produced Beikost Only 11% trusted their own cooking ability enough to start with home made Beikost as the only solid food

Among the families studied three groups were found with different feeding practices One group—the largest one of the whole material—preferred home made food only the home cookers (231 children) another group gave only industrially produced foods the jar buyers (65 children) and a third group gave both kinds of food either at the same meal or on different days group mixed (170 children) (Table 1) There was however a marked age dependency the use of jars being more popular the younger the child was

Table 1 *Feeding practices with respect to beikost in 466 children of different age groups*

Age in months	Per cent Home cookers (n=231)	Jar buyers (n=65)	Mixed (n=170)	Sum (n=466)
6–10	16 2	55 4	28 4	15 9
10–12	29 2	21 5	49 3	14 0
12–18	61 2	3 1	35 7	70 1
Sum	49 6	13 9	36 5	100 0

Home made food

The reasons for giving home made food tabulated in Table 2 were dominated by the conviction that specially prepared solid or semisolid foods for children were not necessary The family s own food was cheaper (39 2%) better (31 9%) and more tasteful (26 9%) than canned food The children s dislike of canned foods was also a factor of some importance more in older children than in younger ($p<0.01$)

Canned food

Parents giving canned food did it because they felt that their own food was not adequate for their children or that the family s eating time was not suitable (46 0% and 30 2% respectively) (Table 3) The matter of convenience was also important for families using

Table 2 *Reasons for giving home made food in per cent (Home cookers and Mixed)*

	Age of children 6–10 months (n=33)	10–12 months (n=51)	12–18 months (n=317)	Sum (n=401)
No need for special food for the child	63 6	56 9	57 4	57 9
Cheaper	33 3	37 3	40 1	39 2
Better nutrition	33 3	7 5	32 5	31 9

Cheaper	0	0	0	0

canned foods: for 43.4% it was more convenient in a general sense, 17% said it was faster and 11.1% % considered it an easy way to let other persons than the mother feed the child.

Better nutrition through feeding the children with industrially produced foods was an argument used by 29.8%, more frequently for the young children than for the older ones ($p<0.01$). No one regarded it cheaper to use canned foods.

Feeding problems

All three groups were equally satisfied with their way of feeding their children, although about 15% in each group were worried that the children did not get the proper nutrition (Table 4). The frequency of feeding problems

age (2) However in toddlers and older infants home made foods accounted for a larger part of the Beikost as compared to younger infants thus in age group 12–18 months 61 2% got exclusively home made foods (Table 1) This is in agreement with the feeding practices in the United States (2)

Parents who preferred industrially produced Beikost were convinced that this was generally most adequate for the child although aspects of convenience also played an important role On the other hand the home cookers thought that their own table food was as adequate or nutritionally even better than that bought in jars It is interesting to note that 9 5% still believe that the industrially produced baby food contains harmful additives and preservatives in spite of heavy information campaigns by the industry on this matter

Estimates of intakes of calories and different nutrients were not made in this study but we have every reason to believe that no deficiency in these matters exists Studies on child health and nutrition in other areas both nearly and far away have all confirmed that the general health condition of children in Sweden is very good they are taller and heavier than children of corresponding age in other countries the haemoglobin concentration is generally satisfying only few have mild anemia and the nutritional requirements are well covered (5 6 7 8 9) Feeding problems still occur but do very seldom depend on lack of food Instead they exist among children who eat too little according to their parents opinion i e problems that are based on an emotional and behavioural level (4 10 11)

Such problems were reported in the present study too but with no consistent association with feeding practices

The fact that social and economic factors to a very small extent seem to influence the choice of food for the children may imply that the economic situation among these families was so good that they could allow themselves a freedom of choice without deeper impact on their standard of living Instead it seems that the mother s own activities interest knowledge and ideas of how to feed children are decisive for her choice

So it is obvious that although the home cookers had a less complete supply of household machines they were more interested in household work like shopping baking and cooking and this did not exhaust them as much as it did the jar buyers

Information about baby food and nutrition is offered to parents from many quarters today both private and offcial ones Best resources in these matters are owned by the food industries Their information reach their customers by advertising and publicity campaigns in magazines and shops as well as by pamphlets sent directly to parents and furthermore also through professionals As a result information given by the food industries is the parents dominating source of knowledge about their children s nutrition and about feeding practices Even parents who preferred home made food used the food industries as their main source of information Under these circumstances it is of course most important that the information and the sales promotion activities by the baby food industries are of a very high quality and that they follow certain basic ethical principles These should protect the parents not only from getting false and biased facts but also against unduly persuasive advertising In a few countries e g in Sweden paediatricians as medical consultants to the industry have already formulated such principles (Medical Standards for Marketing of Infant Foods) which have been accepted by the industry (1) In other countries the development of such principles is in progress

Nevertheless information about nutrition and feeding practices should not be left solely to the industries no matter how good it is The primary responsibility for such information lies on the country s health authorities which consequently should make non commercial information material available The Child Health Centres have a traditional and

Table 6 *Sources of information about nutrition and feeding practices of babies*

Sources of information	Per cent Home cookers ($n=231$)	Jar buyers ($n=65$)	Mixed ($n=170$)	Sum ($n=466$)	Statistical difference between the groups
Baby food industry	46.8	76.9	58.8	55.4	$p<0.001$
Experience from older children	47.6	43.1	35.9	42.7	NS

Courses education	19.0	18.5	21.2	19.7	NS
Common sense	11.3	3.1	13.5	10.9	NS
Other sources	5.2	6.2	4.7	5.2	NS

in general was the same in the three groups although difficulties with the children's weight gain were experienced more frequently by the mixers ($p<0.01$) The mothers estimated knowledge and confidence in nutritional matters were the same for all three groups

Socio economic factors

The distribution of various socio economic factors with respect to the three feeding groups is shown in Table 5 The parents education and the mothers working seemed to have no influence on the choice of way of feeding and the amount of money spent on food did not differ between the groups (the family size did not differ either) All families had an extensive supply of helping devices although the jar buyers had more drying and ironing machines

Children of jar buyers were more often at home during the day ($p<0.001$) and more often always took their meals at home ($p<0.05$) The home cooking mothers often planned their shopping and did not buy on impulse ($p<0.01$) and furthermore they were doing more heavy household work e g baking ($p<0.001$) As a consequence perhaps they had not so much time for social contacts ($p<0.05$) but they were not so tired from their daily work as the jar buyers ($p<0.001$)

Sources of information

From Table 6 it is evident that information from the industries was the most important source for the parents knowledge about nutrition and feeding of babies irrespectively of their feeding practices This dominance was more marked among the jar buyers than in the two other groups ($p<0.001$) Then came experience from having older children and the information from Child Health Centres No difference regarding the sources of information was found with respect to the various age groups of children

DISCUSSION

It is easily conceivable that the rapid development of the baby food industry has influenced the feeding practices of children This is most apparent concerning breastmilk substitutes used for non breastfed infants in Sweden practically all are fed industrially produced infant formulas In the families studied about 80% used industrially produced Beikost—exclusively or in part—when foods other than milk were introduced (Table 1 age group 6–10 months) The age of introducing Beikost (=3–4 months) was later than in the United States where most infants receive such food by 6 weeks of age and many by 4 weeks of

age (2) However in toddlers and older infants home made foods accounted for a larger part of the Beikost as compared to younger infants thus in age group 12–18 months 61 2% got exclusively home made foods (Table 1) This is in agreement with the feeding practices in the United States (2)

Parents who preferred industrially produced Beikost were convinced that this was generally most adequate for the child although aspects of convenience also played an important role On the other hand the home cookers thought that their own table food was as adequate or nutritionally even better than that bought in jars It is interesting to note that 9 5% still believe that the industrially produced baby food contains harmful additives and preservatives in spite of heavy information campaigns by the industry on this matter

Estimates of intakes of calories and different nutrients were not made in this study but we have every reason to believe that no deficiency in these matters exists Studies on child health and nutrition in other areas both nearly and far away have all confirmed that the general health condition of children in Sweden is very good they are taller and heavier than children of corresponding age in other countries the haemoglobin concentration is generally satisfying only few have mild anemia and the nutritional requirements are well covered (5 6 7 8 9) *Feeding problems* still occur but do very seldom depend on lack of food Instead *they exist among* children who eat too little according to their parents opinion i e problems that are based on an emotional and behavioural level (4 10 11)

Such problems were reported in the present study too but with no consistent association with feeding practices

The fact that social and economic factors to a very small extent seem to *influence the* choice of food for the children may imply that the economic situation among these families was so good that they could allow themselves a freedom of choice without deeper impact on their standard of living Instead it seems that the mother s own activities interest knowledge and ideas of how to feed children are decisive for her choice

So it is obvious that although the home cookers had a less complete supply of household machines they were more interested in household work like shopping baking and cooking and this did not exhaust them as much as it did the jar buyers

Information about baby food and nutrition is offered to parents from many quarters today both private and offcial ones Best resources in these matters are owned by the food industries Their information reach their customers by advertising and publicity campaigns in magazines and shops as well as by pamphlets sent directly to parents and furthermore also through professionals As a result information given by the food industries is the parents dominating source of knowledge about their children s nutrition and about feeding practices Even parents who preferred home made food used the food *industries* as their main source of information Under these circumstances it is of course most important that the information and the sales promotion activities by the baby food industries are of a *very high quality* and that they follow certain basic ethical principles These should protect the parents not only from getting false and biased facts but also against unduly persuasive advertising In a few countries e g in Sweden paediatricians as medical consultants to the industry have already formulated such *principles* (Medical Standards for Marketing of Infant Foods) which have been accepted by the industry (1) In other countries the development of such principles is in progress

Nevertheless information about nutrition and feeding practices should not be left solely to the industries no matter how good it is The primary responsibility for such information lies on the country s health authorities which consequently should make non commercial information material available The Child Health Centres have a traditional and

important role in advising parents in infant feeding Considering the apprehension of feed ing management often revealed by the mothers and also the relatively high frequency of feed ing problems reported it seems wise to educate and support the Child Health Centres towards a more active participation on nutri tional matters In this way they will perhaps reach a proper leading role as a source of knowledge for parents about the nutrition and feeding practices of their children

LINEAR GROWTH OF CHILDREN WITH LIMB DEFORMITIES FOLLOWING EXPOSURE TO THALIDOMIDE IN UTERO

C G D BROOK S N JARVIS and C G H NEWMAN

From the Departments of Paediatrics The Middlesex Hospital Wolfson Centre Institute of Child Health and Westminster Hospital London England

ABSTRACT Brook C G D Jarvis S N and Newman C G H (The Middlesex Hospital Wolfson Centre and Westminster Hospital London England Linear growth of children with limb deformities following exposure to thalidomide in utero Acta Paediatr Scand 66 673 1977 —The growth of 202 children exposed to thalidomide in utero and having upper (139 children) or lower (63 children) limb deformities has been assessed towards the end of pre pubertal growth The analyses show that children exposed to thalidomide are shorter than normal children but grow at a normal velocity later These findings may help in consideration of the mechanism by which thalidomide exerted its teratogenic effect Analyses of growth may find a wider use in the retrospective assessment of drugs which are potentially harmful in pregnancy

KEY WORDS Thalidomide environmental teratogens growth limb deformities

In 1961 attention was first drawn to the birth in the preceding two years of a number of children with various limb deformities which were attributed to the administration of thalidomide to mothers in early pregnancy (3) Despite extensive study the mechanism by which these occurred remains obscure (8) This paper reports the growth of some of these children in late childhood

MATERIALS AND METHODS

Cross sectional data were obtained from 0 children (115 boys 87 girls) aged 8 to 14 years 63 of them (36 boys 7 girls) had deformities of the lower limbs and the remainder of the upper limbs with normal lower limbs In the former sitting heights were recorded and in the latter heights were measured standing using standard anthropometric techniques (7)

In 10 boys and 1 girls longitudinal data on height were available between ages 8 and 1 3 of the boys and 1 of the girls were seen twice at annual intervals but the remainder were followed for 3 (3 boys girls) 4 (4 boys 6 girls) and 5 years (7 boys 1 girl) The measurements were plotted on standard charts and heights at annual intervals were taken from the straight lines connecting the points Height velocities were calculated in individual cases from the differences between the yearly estimates Since the children were of different ages the number of observations at any one age vary between 4 and 6

6 boys with lower limb deformities were followed longitudinally for a minimum of 2 years each and sitting height velocities were obtained in the same way

All data were compared to standard values (6) and the results are presented in terms of standard deviation scores (S D S) which were calculated in each case from the formula

$$\text{S D S} = \frac{x - \bar{X}}{s}$$

where x is the measurement $\bar{X}$ is the mean at that age and s the standard deviation

RESULTS

Table 1 shows the results of analysis of the cross sectional data All groups of children were significantly shorter than normal although the differences between the groups were not significant at the 5% level There remains nevertheless a suggestion that the growth of children with lower limb deformities was more severely affected than that of children with upper limb deformities

The means of the height velocities for the

important role in advising parents in infant feeding Considering the apprehension of feed ing management often revealed by the mothers and also the relatively high frequency of feed ing problems reported it seems wise to educate and support the Child Health Centres towards a more active participation on nutri tional matters In this way they will perhaps reach a proper leading role as a source of knowledge for parents about the nutrition and feeding practices of their children

In 10 boys and 1? girls longitudinal data on height were available between ages 8 and 1? 3 of the boys and 1 of the girl were seen twice at annual intervals but the remainder were followed for 3 (3 boys girls) 4 (4 boys 6 girls) and 5 years (boys 1 girl) The measurements were plotted on standard charts and heights at annual intervals were taken from the straight lines connecting the points Height velocities were calculated in individual cases from the differences between the yearly estimates Since the children were of different ages the number of observations at any one age vary between 4 and 6

6 boys with lower limb deformities were followed longitudinally for a minimum of 2 years each and sitting height velocities were obtained in the same way

All data were compared to standard values (6) and the results are presented in terms of standard deviation scores (S D S) which were calculated in each case from the formula

$$S\,D\,S = \frac{x - X}{s}$$

where x is the measurement X is the mean at that age and s the standard deviation

RESULTS

Table 1 shows the results of analysis of the cross sectional data All groups of children were significantly shorter than normal although the differences between the groups were not significant at the 5% level There remains nevertheless a suggestion that the growth of children with lower limb deformities was more severely affected than that of children with upper limb deformities

The means of the height velocities for the

Table 1 *Standard deviation scores of heights and sitting heights of children exposed to thalidomide in utero*

	No of children	Height or sitting height		χ^2	*P*
		Mean	S D		
Boys with upper limb deformity	69	−0 68	1 19	24 16	<0 001
Girls with upper limb deformity	48	−0 71	1 32	36 78	<0 001
Boys with lower limb deformity	36	−2 21	1 77	345 83	<0 001
Girls with lower limb deformity	27	−1 60	1 36	135 4	<0 001

children with upper limb deformities are shown in Table 2 These means correspond closely to the standard values at the various ages This indicates that the children although short are growing normally There were insufficient data to perform these calculations for the sitting height velocities of the children with lower limb deformities but the mean S D S of their sitting height velocities was +1 30 S D 1 28 which does not differ significantly from zero

DISCUSSION

The finding that children exposed to thalidomide in utero have a reduction in their growth potential is a new one It highlights the fact that the effects of thalidomide were not all or none This may have some bearing on the mechanism by which thalidomide caused its teratogenic effects which is not understood at all at the present time

Apart from the obvious limb deformities many body systems were affected including endodermal structures (intestinal atresias absence of appendix or gall bladder) mesodermal structures (skeleton heart kidneys genitalia) and ectodermal structures (cranial nerves eyes ears) Spinal changes have become clinically more apparent over the years and may influence stature (1) These changes included mild to moderate kyphoscoliosis abnormal epiphyseal plates or rarely fusion of *anterior vertebral bodies over several segments*

Spinal curvature of mild or moderate degree was noted in a few of our patients In the majority this seemed to be postural but X ray changes were found in 10 of the children with obvious deformities or symptoms in 5 of the

Ref 5

group with lower limb deformities and in 5 of the group with upper limb deformities The heights of these children appeared randomly distributed in the groups as a whole We conclude therefore that whilst spinal changes may have contributed to short stature in a few children a more basic defect was responsible in the majority

The children of this series were apparently growing normally between the ages of 8 and 12 which rules out endocrine and other pathological causes for their short stature Nevertheless there was one child in this series (not included in the analysis) who had growth hormone deficiency which is now being treated (J M Tanner personal communication) The growth of the children is compatible with the hypothesis that thalidomide damaged the growth process at a time when subsequent catch up was not possible In this respect the children are similar to those who suffer prolonged intrauterine starvation in the second trimester and do not catch up (2) The later growth pattern of such children is identical to the presently reported one (5) The birth weights of the children in this series are not available but as standards for children missing limbs are not available either this point could not be resolved even if the data were there It is the clinical impression of the authors that the limb defects apart these children were distressingly normal as infants It seems unlikely that the growth findings are simply the result of low birth weight as in no other respect do the children resemble small for dates patients

The findings have implications for the assessment of teratogenicity of other substances administered to pregnant mothers At present the teratogenic effects of alcohol of smoking of anticoagulants and especially of anticonvulsants are under scrutiny (4) Growth analyses of the type reported in this paper may help in consideration of whether such substances are harmful to the fetus Measurements of growth are relatively easily performed and have the advantage of being able to be applied retrospectively

THE EARLY DETECTION OF PNEUMOTHORAX WITH TRANSTHORACIC IMPEDANCE IN NEWBORN INFANTS

G NOACK and U FREYSCHUSS

From the Department of Pediatrics Karolinska Institutet at S t Goran s Children s Hospital and the Department of Clinical Physiology Serafimer Hospital Stockholm Sweden

ABSTRACT Noack G and Freyschuss U (The Department of Pediatrics Karolinska Institutet at S t Goran s Children s Hospital and the Department of Clinical Physiology Serafimer Hospital Stockholm Sweden) The early detection of pneumothorax with trans thoracic impedance in newborn infants Acta Paediatr Scand 66 677 1977 —During the treatment of IRDS with assisted ventilation pneumothorax is a common and dangerous com plication where an early diagnosis is important for the successful treatment In this case report the continuous monitoring of transthoracic electrical impedance has proven to be a sensitive and non invasive method to detect the development of pneumothorax long before clinical signs are manifest

KEY WORDS pneumothorax newborn transthoracic electrical impedance

Assisted ventilation is indispensible in the treatment of the idiopathic respiratory distress syndrome of the newborn and especially the introduction of continuous positive airway pressure (CPAP) by Gregory et al (6) has added greatly to the ventilatory efficiency Unfortunately neither prolonged ventilatory assistance nor CPAP with spontaneous ven tilation are without complications Pneumothorax and pneumomediastinum occuring with or without mechanical ventilation are one of the leading immediate causes of mortality (6) The need for an early diagnosis of pulmonary complications is thus urgent This report shows that the measurement of transthoracic electrical impedance is a valuable technique for the early detection of pneumothorax

METHODS

Transthoracic electrical impedance was measured by a Minnesota Impedance Cardiograph Model 304 A A tetra polar electrode system was used aluminium electrodes with mylar adhesive backing were placed circumferenti ally around the patient s neck and chin and at the level of the diaphragm The outer electrodes 1 and 4 were con nected to a constant current source providing 4 mA at a *frequency of 100 kHz* From the two inner electrodes 2 and 3 the standing impedance i e basal impedance (Z_0) was read on a digital display and the first deriva tive of the diminution of Z_0 occurring during the cardiac *cycle* (dZ/dt) was displayed on a recorder A crystal micro phone was placed at the second left intercostal space to record a phonocardiogram thus facilitating a proper tim ing of the 2nd heart sound The electrodes radiolucent to X ray could be kept in place for as long as 10 to 14 days

Stroke volume was calculated according *to a modifi* a tion of the method of Kubicek et al (7) utilizing the follow ing formula

$$\text{Stroke volume} = \rho \left(\frac{L}{Z}\right)^2 T \; dZ/dt \; \text{min}$$

where

- ρ = resistivity of blood (determined from the hemato crit)
- L = distance (cm) between the inner electrodes 2 and 3
- Z_0 = the basal thoracic impedance (ohm)
- T = the ventricular ejection time (sec)
- dZ/dt = the maximum deflection of impedance trace *from* zero line (ohm/sec)

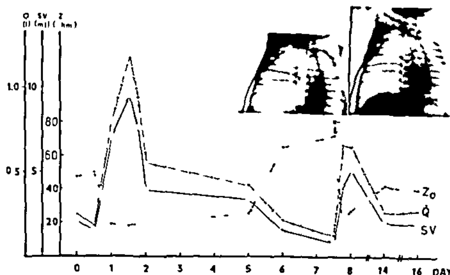

Fig 1 Consecutive transthoracic impedance data of case 1 $\dot{Q}$=cardiac output SV=cardiac stroke volume Z_0=basal impedance X ray pictures demonstrate pneumothorax and the effect of subsequent pleural suction

On a multichannel graphic recorder (Siemens Elema Mingograph 34) three output signals were recorded ECG dZ/dt and phonocardiogram As baseline shifted with respiration only tracings at the zero line were selected for calculation i e the same procedure as during recording in apnoea

Arterial blood gases (P_{aO_2} P_{aCO_2}) and pH were analyzed with a blood micro system (BMS2 Radiometer Copenhagen)

CASE REPORT

Case 1 Twin no 1 a premature boy weighing 1 340 g and with Apgar 4 breathed spontaneously after external stimulation He was brought to the intensive care unit with repeated episodes of apnoea A catheter was inserted into the abdominal aorta through an umbilical artery He was treated with external stimulation and 80% oxygen but cyanosis and bradycardia reappeared CPAP was started but a P_{aO_2} of 6 6 kPa (50 mmHg) and a base excess of 11 mmol/l were an indication for endotracheal intubation and assisted ventilation with respirator (Servo Ventilator Siemens Elema) with IPPB (intermittent positive pressure breathing) and PEEP (positive end expiratory pressure) of +4 cmH O

X ray film showed atelectases in both lungs associated with a low basal impedance a large stroke volume and cardiac output (Fig 1) which might reflect an increased shunt After

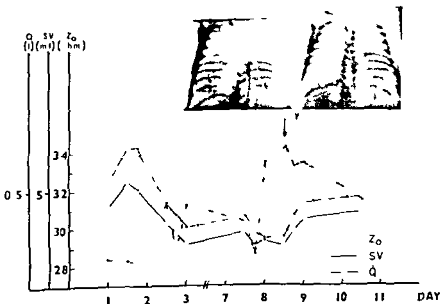

Fig 2 Sequence of impedance data and X rays of case 2 Abbreviations as in Fig 1

mechanical ventilation for four days the basal impedance slowly increased and the stroke volume and cardiac output decreased The blood gases were normal with a P_{ao} of 11 6 kPa (87 mmHg) and a pH of 7 34 Between the 5th and the 6th day of birth the impedance rose to over 60 ohm without clinical signs of distress In the middle of the 7th day the infant became cyanotic and blood pressure fell X ray then showed a right pneumothorax with dislocation of the heart (Fig 1) Stroke volume and cardiac output were under these circumstances low With 90% oxygen in the inspiratory gas P_{O_2} was 10 1 kPa (75 mmHg) and pH 7 45 After thoracocentesis and permanent suction the infant recovered and impedance data normalized

Case 2 A newborn boy birth weight 1765 g was delivered by caesarean section Due to apnoea endotracheal intubation and ventilation with respirator was commenced at the intensive care unit Admission Z_0 was 28 4 ohm and evidence of bilateral infiltration was noted on the X ray P_{O_2} was 8 5 kPa (64 mmHg) During the following days with mechanical ventilation and PEEP+4 cmH_2O Z_0 rose to about 30 ohm and chest film was clearer The basal impedance remained at this level until the 7th day after birth when Z_0 rose from 28 6 to 34 4 ohm X ray demonstrated a partial pneumothorax but clinical signs were absent

On the 8th day the infant developed cyanosis and bradycardia X ray showed pneumothorax at the right side and P_{aO_2} was 6 6 kPa (50 mmHg) Z_0 dropped after thoracocentesis and permanent suction The hospital course is illustrated in Fig 2 The infant later redeveloped pneumothorax and died

DISCUSSION

The use of transthoracic impedance as a reliable and sensitive non invasive measure of air fluid changes in thorax is well documented in both experimental and clinical studies (1–4 9–13) Pulmonary infiltrate and pleural effusion decrease basal impedance positive pressure ventilation and pneumothorax increase impedance The impedance variations during respiration has been used for apnoea monitoring (3) The sensitivity of the method to detect alterations in intrathoracic fluid volumes has been emphasized by Pomerantz et al (11) who observed a fall in basal impedance 45 min before other parameters such as blood gases central venous pressure and pulmonary compliance significantly changed

For newborn infants with pulmonary complications it is important to have a continuous monitor of a non invasive type which does not disturb their normothermic atmosphere and which does not interfere with therapy or other diagnostic interventions e g X ray

The present report demonstrates the pitfall of the early phase of a developing pneumothorax where obvious clinical signs are absent and hence therapy might be delayed Several X rays of the chest are needed because of the initial pulmonary dysfunction the number of radiation exposures will greatly increase if secondary pulmonary complications are added Thus X ray was performed twelve times in case 1

In our two cases a rapid significant increase in basal impedance was associated with pneumothorax and falling impedance values with pleural suction The accuracy of the stroke volume – cardiac output data in the present study cannot be validated It can only be assumed that the initial large stroke volume noted in case no 1 might reflect an increased shunt in accordance with the observation that in patients with left to right shunts the impedance cardiac output values correlated well with pulmonary blood flow (8)

Normal values of basal impedance are not available due to its dependance on e g thoracic volume In an ongoing study healthy neonates are followed after vaginal delivery and caesarian section respectively (5) During the first 36 hours the mean intraindividual changes in basal impedance were 2 1 (S D ±

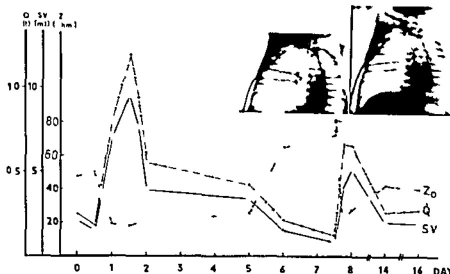

Fig 1 Consecutive transthoracic impedance data of case 1 $\dot{Q}$=cardiac output *SV*=cardiac stroke volume Z_0=basal impedance X ray pictures demonstrate pneumothorax and the effect of subsequent pleural suction

On a multichannel graphic recorder (Siemens Elema Mingograph 34) three output signals were recorded ECG d_z/dt and phonocardiogram As baseline shifted with respiration only tracings at the zero line were selected for calculation i e the same procedure as during recording in apnoea

Arterial blood gases (P_{O_2} P_{CO_2}) and pH were analyzed with a blood micro system (BMS3 Radiometer Copenhagen)

CASE REPORT

Case 1 Twin no 1 a premature boy weighing 1340 g and with Apgar 4 breathed spontaneously after external stimulation He was brought to the intensive care unit with repeated episodes of apnoea A catheter was inserted into the abdominal aorta through an umbilical artery He was treated with external stimulation and 80% oxygen but cyanosis and bradycardia reappeared CPAP was started but a P_{aO_2} of 6 6 kPa (50 mmHg) and a base excess of 11 mmol/l were an indication for endotracheal intubation and assisted ventilation with respirator (Servo Ventilator Siemens Elema) with IPPB (intermittent positive pressure breathing) and PEEP (positive end expiratory pressure) of +4 cmH O

X ray film showed atelectases in both lungs associated with a low basal impedance a large stroke volume and cardiac output (Fig 1) which might reflect an increased shunt After

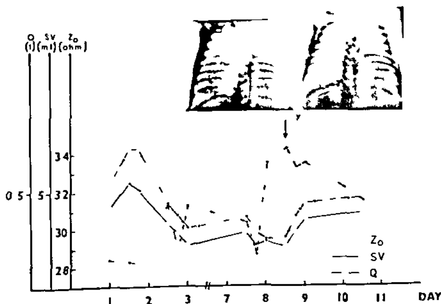

Fig 2 Sequence of impedance data and X rays of case 2 Abbreviations as in Fig 1

SERUM LEVELS OF THYROTROPIN THYROXINE AND TRIIODOTHYRONINE IN FULLTERM SMALL FOR GESTATIONAL AGE AND PRETERM NEWBORN BABIES

B BROCK JACOBSEN H J ANDERSEN B PEITERSEN H DIGE PETERSEN and L HUMMER

From the University Clinic of Paediatrics Children s Hospital Fuglebakken and from the Department of Nuclear Medicine Rigshospitalet Copenhagen Denmark

ABSTRACT Jacobsen B B Andersen H J Peitersen B Dige Petersen H and Hummer L (The University Clinic of Paediatrics Children s Hospital Fuglebakken and the Department of Nuclear Medicine Rigshospitalet Copenhagen Denmark) Serum levels of thyrotropin thyroxine and triiodothyronine in fullterm small for gestational age and preterm newborn babies Acta Paediatr Scand 66 681 1977.—Simultaneous serum concentrations of TSH total thyroxine (T_4) and triiodothyronine (T_3) were determined in 93 fullterm (FT) 37 small for gestational age (SGA) and 38 preterm (PT) babies with a post natal age from 2 to 144 hours In addition TSH T_4 and T_3 concentrations were measured in cord sera from 27 FT 4 SGA and 5 PT babies and in venous blood from 20 mothers at delivery Cord blood concentrations of TSH were higher and T_4 and T_3 concentrations were lower than seen in the mothers Serum concentrations of TSH were high during the first day of life followed by a decline There was no statistically significant difference between serum TSH concentrations of the three groups of newborns On the 5th day of life no elevated serum TSH values were found in any of the groups (TSH<5mU/l) Serum concentrations of thyroid hormones increased after birth and reached maximum levels within 24 hours in all groups The relative increases above cord level were of the same magnitude in the newborns Two times for serum T and six times for serum T_3. The thyroid hormone concentrations in blood samples from FT babies decreased from the second day of life whereas in low birth weight newborns the decreases were more variable The serum levels of T and T_3 were significantly different in the three groups of newborns the highest values were seen in FT and the lowest values in PT babies In contrast the ratios between molar serum concentrations of T and T were found to be highest in PT lower in SGA and lowest in FT babies approaching maternal values during the first week of life The data are discussed with regard to hormone secretion thyroxine binding capacity and peripheral T to T_3 conversion in the three groups of newborns It is concluded that from day 5 after birth serum TSH determinations alone or in combination with serum T_4, seem to be the method of choice in screening for congenital hypothyroidism

KEY WORDS Thyrotropin thyroxine triiodothyronine preterm small for gestational age fullterm newborns

In fullterm newborn babies the postnatal hypersecretion of thyrotropin (TSH) has been described by several authors (7 12 13 26) the subsequent increases in serum concentrations of protein bound iodine (PBI) thyroxine (T_4) and triiodothyronine (T_3) are also well known (1 8 11 29 32) In lowbirth weight neonates however simultaneous values of serum TSH T_4 and T_3 have not been published Because of low serum T_4 concentrations in preterm and small for gestational age babies (23 33) these newborns may be falsely suspected of neonatal hypothyroidism

The clinical diagnosis of hypothyroidism during the neonatal period is difficult and often overlooked (3) and neonatal screening pro-

3 8) ohm and hence the present data could be appreciated as significant changes

Transthoracic impedance techniques have been used for apnoea monitoring in neonatal intensive care units Due to variations in apparatus many of which are home made and due to different electrode techniques data on basal impedance if available cannot be extrapolated to other equipment To our knowledge an evaluation of basal impedance changes obtained with a commercially available apparatus as done above against a healthy control material has not been reported A method is hereby offered for the detection of changes in the respiratory state of an infant long before they are clinically significant

above this range The serum TSH levels in PT and SGA neonates were however so highly variable that no statistically significant decrease could be shown after 24 hours After the 5th day of life all values were below 5 mU/l

In cord sera the TSH concentrations of PT and SGA babies seemed to be higher than in FT but few low birth weight babies were studied Maternal TSH values were within the normal range

Serum T_4 concentrations (Table 3)

In the FT newborns maximum values of serum T_4 were found about 24 hours after delivery and they were about twice those of cord blood (Fig 1) After this time a significant decrease in serum T_4 concentrations appeared ($p<0\ 01$) The maximum serum T_4 values of PT and SGA newborns were about twice the cord levels as in FT babies The serum T_4 concentrations in the 3 groups of newborns differed significantly ($p<0\ 001$) the lowest

cedures for congenital hypothyroidism will therefore be of increasing importance (2 16)

The present study therefore was undertaken to investigate the changes in simultaneous serum levels of TSH T_4 and T_3 in normal preterm and small for gestational age newborns compared to fullterm newborn babies during the first six days of life

MATERIALS AND METHODS

The clinical data are presented in Table 1 Venous blood samples were obtained from 93 fullterm (FT) babies 37 small for gestational age (SGA) babies with gestational age from 37 to 40 weeks and from 38 preterm (PT) appropriate for weight babies with gestational age from 27–36 weeks The parents were informed and consent obtained The birth weights of the three groups differed significantly ($p<0\ 001$) Gestational age and maturity were assessed as previously reported (19 20) The postnatal age ranged from 2 to 144 hours median values tended to be lower in low birth weight newborns but did not differ significantly from that of FT babies ($p>0\ 05$) In addition cord blood samples were obtained from 27 FT 4 SGA and 5 PT babies Infants with a history of fetal distress respiratory distress syndrome or major congenital abnormalities were excluded from the study Finally venous blood samples were obtained from 20 mothers at the delivery The infants of these mothers were FT and included in the present study

Only one blood sample was obtained from each infant Unfortunately in some cases there was only material for measurements of two of the hormones one of which was T_4 Blood was usually drawn in the morning centrifuged immediately and serum was stored at −20° until analyses were performed *Serum TSH* was measured by double antibody RIA technique as previously reported (10 20) The detection limit of the assay is 0 2 mU/l and in the calculations values below the sensitivity limit were expressed as 0 1 mU/l The serum TSH concentration in adults is <3 5 mU/l *Serum T_4* was determined using a modification of the competitive binding technique (Tetralute Ames) reported by Braverman et al (4) and elsewhere by us (20) Normal adult range of serum T_4 concentration is 60–137 nmol/l *Serum T_3* was measured radioimmunologically (17 20) Normal adult range of serum T_3 concentration is 1 10–2 40 nmol/l All analyses were performed in duplicate

A normal distribution of the thyroid variables was not seen A non steady state of hormone secretion during the first days of life and the differences (for obvious reasons) with regard to postnatal age and number of infants in the groups of newborns make a comparison between the hormone levels difficult Very low p values however support the assumption that the null hypothesis" (31) (no true differences between the groups) must be discharged The following non parametric statistical tests were used The Mann Whitney test the Kruskal Wallis one way analysis of variance and the Spearman rank correlation (R) (9 31)

RESULTS

Serum TSH concentration (Table 2)

In all the FT babies maximum values of serum TSH were seen within 24 hours after birth and subsequently a significant decrease with postnatal age was observed ($p<0\ 0005$) normal adult levels were reached from 72 to 96 hours after delivery In low birth weight newborns high serum TSH concentrations were observed within the first 24 hours of life as in FT babies and the TSH values were not significantly different from those of FT ($p\geq 0\ 2$) a few TSH values below the range of FT were observed none had a serum TSH (0–24 hours)

cedures for congenital hypothyroidism will therefore be of increasing importance (2 16)

The present study therefore was under taken to investigate the changes in simultaneous serum levels of TSH T_4 and T_3 in normal preterm and small for gestational age newborns compared to fullterm newborn babies during the first six days of life

MATERIALS AND METHODS

The clinical data are presented in Table 1 Venous blood samples were obtained from 93 fullterm (FT) babies 37 small for gestational age (SGA) babies with gestational age from 37 to 40 weeks and from 38 preterm (PT) appropriate for weight babies with gestational age from 27–36 weeks The parents were informed and consent obtained The birth weights of the three groups differed significantly ($p<0\ 001$) Gestational age and maturity were assessed as previously reported (19 20) The post natal age ranged from 2 to 144 hours median values tended to be lower in low birth weight newborns but did not differ significantly from that of FT babies ($p>0\ 05$) In addition cord blood samples were obtained from 27 FT 4 SGA and 5 PT babies Infants with a history of fetal distress respiratory distress syndrome or major congenital abnormalities were excluded from the study Finally venous blood samples were obtained from 20 mothers at the delivery The infants of these mothers were FT and included in the present study

Only one blood sample was obtained from each infant Unfortunately in some cases there was only material for measurements of two of the hormones one of which was T_4 Blood was usually drawn in the morning centrifuged immediately and serum was stored at −20° until analyses were performed *Serum TSH* was measured by double antibody RIA technique as previously reported (10 20) The detection limit of the assay is 0 2 mU/l and in the calculations values below the sensitivity limit were expressed as 0 1 mU/l The serum TSH concentration in adults is <3 5 mU/l *Serum T_4* was determined using a modification of the competitive binding technique (Tetralute Ames) reported by Braverman et al (4) and elsewhere by us (20) Normal adult range of serum T_4 concentration is 60–137 nmol/l *Serum T_3* was measured radioimmunologically (17 20) Normal adult range of serum T_3 concentration is 1 10–2 40 nmol/l All analyses were performed in duplicate

A normal distribution of the thyroid variables was not seen A non steady state of hormone secretion during the first days of life and the differences (for obvious reasons) with regard to postnatal age and number of infants in the groups of newborns make a comparison between the hormone levels difficult Very low p values however support the assumption that the null hypothesis (31) (no true differences between the groups) must be discharged The following non parametric statistical tests were used The Mann Whitney test the Kruskal Wallis one way analysis of variance and the Spearman rank correlation (R) (9 31)

RESULTS

Serum TSH concentration (Table 2)

In all the FT babies maximum values of serum TSH were seen within 24 hours after birth and subsequently a significant decrease with postnatal age was observed ($p<0\ 0005$) normal adult levels were reached from 72 to 96 hours after delivery In low birth weight newborns high serum TSH concentrations were observed within the first 24 hours of life as in FT babies and the TSH values were not significantly different from those of FT ($p\geq 0\ 2$) a few TSH values below the range of FT were observed none had a serum TSH (0–24 hours)

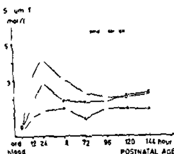

Fig 2 Median values of serum T_3 concentrations during the first 6 days of life in normal fullterm (*FT*) small for date (*SGA*) and preterm (*PT*) babies

serum concentrations of T_4 and T_3 were calculated Median values and range of the T_4/T_3 ratios are shown (Fig 3) The ratio was higher in cord blood than in bloodsamples from day 1 to 6 of life and much higher than observed in maternal blood samples The T_4/T_3 ratio in PT was significantly higher than in SGA babies and their ratios were higher than seen in FT babies ($p<0\ 0005$) The T_4/T_3 ratio decreased by age and approached that of maternal values

DISCUSSION

The present study demonstrates pronounced changes in serum concentrations of TSH and thyroid hormones in FT as well as in SGA and PT newborn babies

In FT babies there was invariably a pronounced early increase and a subsequent decrease in serum TSH values reaching normal adult levels after 2–3 days cord blood levels of TSH were higher than maternal values This agrees with previous reports (7 12 13 14 32) Our finding of a higher TSH level in cord blood of low birth weight babies than seen in FT babies is not in accordance with a previous study by Fisher et al (14) and might be due to the rather small number of cord blood samples from SGA and PT babies in the present study

In low birth weight neonates the serum TSH concentrations did not differ significantly from that of FT babies but the changes in serum TSH in relation to time were more variable compared with the FT neonates After 5 days no elevated serum TSH concentrations were found in any groups This does not seem to be in keeping with the findings of Lemarchand Beraud et al (24) describing a more marked and sustained TSH release in PT (and some SGA) babies with elevated serum TSH concentrations even after one week However the TSH analysis of these authors differs from ours by use of canine serum instead of TSH free human serum for the standard curve Furthermore nothing was reported concerning body temperature All our infants had normal body temperature and many of the low birth weight newborns were in incubator at the time of study The influence of cold (12) could be one cause of the difference between the two materials

The present data of TSH values in PT babies *during the first week of life* and the normal TSH response to exogenous thyrotropinreleasing hormone (TRH) in PT (and SGA) neonates (20) support the hypothesis of a maturation of the fetal hypothalamicpituitary system prior to the 27th week of gestation (14 18)

The serum concentrations of thyroid

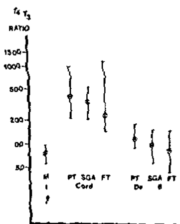

Fig 3 Median values and range of the ratios between molar serum concentrations of T_4 and T_3 in fullterm (*FT*) small for gestational age (*SGA*) and preterm (*PT*) new born babies and in the mothers at delivery (*Cord* cord sera *day 1–6* serum samples from babies 2 to 144 hours of age)

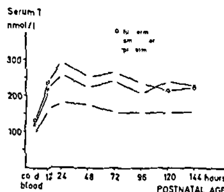

Fig 1 Median values of serum T_4 concentrations during the first 6 days of life in normal fullterm (*FT*) small for date (*SGA*) and preterm (*PT*) babies

values were observed in PT No statistically significant decrease after 24 hours could be shown in PT and SGA babies In all groups the median T_4 level remained above normal adult level throughout the period of study

In cord sera the serum T_4 concentrations of all newborns were significantly lower than maternal values ($p<0\ 001$) and seemed to be lower in the low birth weight newborns than in FT

Serum T_3 concentrations (Table 4)

In the FT babies maximum T_3 values were seen about 24 hours after birth and the maximum level was 6–7 times the cord blood level The subsequent decrease in relation to time was significant ($p<0\ 001$) (Fig 2) In the PT and SGA neonates a marked increase during the first 24 hours, 6–7 times the cord blood level was observed as in FT but no significant decrease could be shown between day 2–6 The serum T_3 levels of SGA neonates were significantly lower than those of FT and those of PT were even lower ($p<0\ 001$) On day 5–6 the median serum T_3 concentration of FT and SGA newborns was in the high normal adult range whereas in PT the median serum T_3 remained lower

In cord blood the same distribution between the groups was observed as for serum T_4 PT babies seemed to have the lowest values

Relationship between serum concentrations of T_4 and T_3

In cord blood of FT babies the higher T_4 levels correlated with the higher T_3 levels ($R=0\ 54$ $p<0\ 01$) and this seemed also to be the case in PT and SGA babies During the neonatal period (day 1 to 6) a positive correlation was found in all groups ($R=0\ 59$ $0\ 79$ and $0\ 82$ in FT SGA and PT babies respectively $p<0\ 001$)

In all subjects with measurement of both thyroid hormones the ratios between molar

hormones were low in cord sera and increased during the first 24 hours after birth Previously similar findings have been reported in FT babies (1 7 11 25 26 32) The relative serum T_3 increase was more marked than the serum T_4 increase corresponding to the higher relative T_3 response in newborns after exogenous TRH stimulation (20)

The total serum concentrations of T_4 and T_3 during this first week of life were highest in FT and lowest in PT babies whereas intermediate values appeared in SGA babies Previously lower serum PBI and T_4 concentrations have been observed in some low birth weight newborns (21 27 30) and some studies have demonstrated that the total and free serum T_4 and thyroxinebinding globulin (TBG) concentrations increase progressively with gestational age (14 18) Therefore the low values found in PT in the present study may be due to low serum concentrations of TBG this may be the reason for the lower thyroid hormone values in SGA babies too Further studies are in progress

In all groups of newborns a positive correlation was found between serum concentrations of T_4 and T_3 However not only the serum levels were different but also the *ratios* between serum T_4 and serum T_3 differed in FT SGA and PT newborns Previous studies of FT infants have demonstrated a high ratio of serum T_4 to serum T_3 concentrations in cord blood as compared with maternal values and a pronounced decrease after delivery (1 11) In cord blood of PT babies even higher T_4/T_3 ratios have been observed although in the fetal thyroid gland the ratio of T_4/T_3 after midgestation is similar to that of adults (15) These observations are in accordance with the results presented The findings agree with the suggestion of a relatively low rate of T_4 to T_3 conversion by extra thyroidal tissue in the fetus as compared to the newborn child (1 11 15 22) When calculating the serum T_4/T_3 ratio of the neonates during the first 6 days of life we found that the ratios differed significantly in the 3 groups with the highest values in PT and lowest values in FT babies This may indicate that a relative T_3 deficiency to some extent continues in low birth weight neonates during the early postnatal period Chopra et al (5) have recently reported high concentrations of reverse triiodothyronine in cord blood and a pronounced decline in FT babies after birth Investigations of the relationship between the serum values of T_4 T_3 and reverse T_3 in the different groups of newborns would be of great interest In addition the reports of a lower serum T_4 and serum T_3 and a higher ratio of T_4/T_3 in PT babies with respiratory distress syndrome than in controls attract attention but require further investigations (6 28)

This study shows that in low birth weight newborns the measurement of serum T_4 alone may falsely indicate primary hypothyroidism After 5 days of age the serum TSH concentration was normal in all newborns including PT and SGA babies We therefore conclude that a supplementary measurement of TSH should be performed from the 5th day of life to exclude the diagnosis of congenital hypothyroidism

ACKNOWLEDGEMENTS

We are grateful for excellent technical assistance by the staff of the two laboratories involved in the project and for valuable secretary help by Miss A Jacobsen

Human TSH for iodination and anti human TSH were kindly donated by the National Pituitary Agency Bethesda USA The human TSH international reference preparation 68/38 was given by the Medical Research Council Holly Hill London Thanks also to the Department of Obstetrics Frederiksberg Hospital from which some of the blood samples were obtained

The study was supported by Statens Laegevidenskabelige Forskningsfond and Dagmar Marshall Foundation

ANTIBODY RESPONSE IN MARASMIC CHILDREN DURING RECOVERY

Z L AWDEH A K KANAWATI[1] and S Y ALAMI[2]

From the Nutrition Research Program and the Department of Clinical Pathology Hospital of the American University of Beirut Beirut Lebanon

ABSTRACT Awdeh Z L, Kanawati A K and Alami S Y (The Nutrition Research Program and the Department of Clinical Pathology Hospital of the American University of Beirut Beirut Lebanon) Antibody response in marasmic children during recovery Acta Paediatr Scand 66 689 1977 —The I II and III antibody responses to tetanus and diphtheria were assessed in marasmic and moderate protein-calorie malnourished children and compared to that of controls The results suggest that during recovery marasmic children are capable of responding adequately to tetanus and diphtheria vaccines

KEY WORDS Antibody response marasmus

Malnutrition is thought to increase the susceptibility of children to infection and the consequences of infectious diseases are likely to be more serious In children suffering from kwashiorkor there is evidence of increased frequency and severity of infections (11) There is also good evidence that both the cellular (14 15) and humoral (9) immunity are depressed in such children The effects of marasmus on immunity in such children is either decreased (12) unchanged or increased (4) The results of studies on the humoral response are also conflicting (1 7)

Marasmus is the most common form of malnutrition in many developing countries (6) it mainly affects infants between the age of 3–12 months The weight of the child suffering from marasmus may fall below 50% of his expected weight for age Treatment requires hospitalization for about three months during which time the child may approach his expected weight for age

In view of the fact that little is known about the effectiveness of vaccines given to marasmic children we decided to assess their immunological response to the triple vaccine by measuring the level of antitetanus and antidiphtheria antibodies in their serum after vaccination On the same samples obtained for the measurement of the levels of antibodies quantitation of IgG IgA and IgM immunoglobulins was performed to determine if they are low in marasmus and if they vary during recovery

MATERIALS AND METHODS

Subjects

The study was conducted on three groups of children between the age of 3–12 months The first group consisted of marasmic children with body weight less than 60% of Boston International Standard The children in this group had marked wasting of subcutaneous tissues with no oedema or any of the other signs of Kwashiorkor They were studied two weeks after admission to the hospital and after the treatment of diarrhea vomiting and electrolytes imbalance which were frequently present

The second group consisted of children admitted to the hospital with moderate protein-calorie malnutrition (PCM) They were non-oedematous with body weight

Table 2 *Mean immunoglobulin levels in malnourished children before and after treatment as compared to controls*

		No of children	% weight for age	Level (g/litre)		
				IgG	IgA	IgM
Marasmus	Before recovery	10	55 0± 4 4	5 75±2 47	0 34±0 23	1 61±0 42
	After recovery	10	77 1± 4 4	7 33±3 43	0 28±0 15	1 52±0 82
Moderate PCM	Before recovery	11	75 1± 5 9	6 52±2 52	0 29±0 19	1 17±0 55
	After recovery	11	88 1±10 9	8 67±3 44	0 24±0 10	1 07±0 35
Control		35	103 0± 7 0	5 69±2 80	0 25±0 19	0 98±0 50

erately malnourished group was not significantly different ($p>0$ 05)

The mean levels of IgG IgA and IgM immunoglobulins are given in Table 2 Since immunoglobulins levels in infants are age dependent the statistical analysis was done by the analysis of covariance (16) There were no significant differences ($p>0$ 05) between the control the marasmic and the moderately malnourished groups for the three immunoglobulin classes IgG IgA and IgM at the start of the treatment or after recovery Furthermore there was no significant difference ($p>0$ 25) between any of the three immunoglobulin levels at the start of treatment and after recovery

DISCUSSION

It has been suggested that the most important two factors that determine the well being of infants in any community are nutritional status and freedom from disease A combination of malnutrition and infections is responsible for the high infant mortality rate in developing countries (8 13) In communities where malnutrition is common there is no clear recommendation as to whether children suffering from malnutrition should be vaccinated In this country and perhaps in other developing countries there is an impression that vaccinating a malnourished child may not be advisable and that it may even be harmful since the response of such children may not be adequate In this respect there is nothing in our data to suggest that marasmic children should not be vaccinated with the triple vaccine since such children are capable of responding normally to this vaccine provided that they are being treated for malnutrition

S=the difference was significant ($p<0$ 05)

between 60–80% of Boston International Standard The malnourished children in both groups were fed S26 humanized milk (Wyeth Laboratories Inc Philadelphia Pa) and mixtures of Laubinia which is a protein enriched cereal food (2) cow s milk and sugar The third group consisted of normal healthy children with a body weight above 90% of the Boston International Standard the children came from the same environment to act as age matched controls There was no control on the diet of children in the control group as they were not hospitalized The weights of the children in three groups were expressed as a percentage of their expected standard weight for age at the start of vaccination using the Boston International Standard as a reference

An initial blood sample was obtained from all children of all groups before receiving the first dose of the triple vaccine Two weeks later a second blood sample was obtained At two weeks interval blood sample drawing was alternated with revaccination until a total of three inoculations (i e given at monthly intervals) had been made and four blood samples obtained On each serum sample obtained the levels of antidiphtheria and antitetanus antibodies as well as that of the IgG IgA and IgM immunoglobulins were determined Since the levels of immunoglobulins in children are age dependent and since the number of children who received the vaccination in the control group was small immunoglobulin levels of 35 children attending the well baby clinic were also determined

Vaccines

Triple vaccine (diphtheria tetanus and pertussis absorbed) was obtained from the Lister Institute Elstree Hearts England Each dose of this preparation contained 30 Lf purified diphtheria toxoid 6 Lf purified tetanus toxoid and 20 000 million *Bordetella pertussis* in 0 5 ml

Tetanus and diphtheria antitoxin titration

The tetanus antitoxin titer was determined by an indirect haemagglutination test as described by Fulthorpe (3) Sheep red blood cells treated with tannic acid were sensitized with tetanus toxoid obtained from the Austrian Institute for Haemoderivate Vienna Antidiphtheria antitoxin levels were also titrated by indirect haemagglutination (17) Sheep red blood cells treated with tannic acid were sensitized with diphtheria toxoid obtained from the Austrian Institute for Haemoderivate Vienna For both titrations the first serum dilution was 1 10

Immunoglobulins quantitation

Immunoglobulin levels were determined by the single radial immunodiffusion test (5) using antibody containing plates purchased from Meloy Laboratories (Springfield Virginia) and locally prepared plates Commercial standards from Meloy Laboratories were used along with international standards obtained from the WHO International Reference Centre for Immunoglobulins Lausanne Switzerland (10)

RESULTS

The mean values of the antitetanus and antidiphtheria for the control and malnourished children are given in Table 1 The data were converted from a nonlinear to a linear scale by expressing the results as log² of titres for statistical analysis Using the *t* test there was no significant difference ($p>0$ 05) between the marasmic the moderateley malnourished and the control group in their primary or secondary responses to either tetanus or diphtheria The tertiary response to diphtheria immunization of both marasmic and moderately malnourished children was significantly higher ($p<0$ 05) than that for the control group The tertiary response of marasmic children to tetanus was significantly higher than that of the control group ($p<0$ 05) while that of the mod

HEMOLYTIC UREMIC SYNDROME

Results of Treatment with Hemodialysis

M EKBERG L HOLMBERG and T DENNEBERG

From the Department of Paediatrics and the Renal Unit Department of Internal Medicine I University of Lund General Hospital Malmo Sweden

ABSTRACT Ekberg M Holmberg L and Denneberg T (Department of Paediatrics and the Renal Unit Department of Internal Medicine I University of Lund General Hospital Malmo Sweden) Hemolytic uremic syndrome Results of treatment with hemodialysis Acta Paediatr Scand 66 693 1977.—The characteristics of the hemolytic uremic syndrome in 7 children living in a well defined area in the south of Sweden are described All the patients had a severe form of the disease and were critically ill The clinical activity could best be followed by measuring blood platelets and urinary FDP Early institution of hemodialysis treatment given almost daily until normalisation of platelet count and urinary output is the most important live-saving measure Full dosage heparin seems not to be necessary Six patients survived and were followed up for 1–7 years When last seen they all had normal renal function and blood pressure

KEY WORDS Hemolysis thrombocytopenia renal insufficiency urinary FDP hemodialysis heparin

The hemolytic uremic syndrome (HUS) is characterised by acute renal failure hemolytic anemia and thrombocytopenia In many parts of the world HUS is now recognised as the most common cause of acute renal insufficiency in children (9 22) In some regions the disease tends to be rather mild with a low mortality (11 19 28) while in others the mortality is considerable (13 20 29) The etiology of the syndrome is unknown and its treatment largely empirical and controversial This paper reports the results of a treatment without full dosage heparin and steroids but with prompt hemodialysis in the event of progressive renal insufficiency

CLINICAL MATERIAL

The material consisted of 7 children (5 girls and 2 boys) treated in the Department of Paediatrics at Malmö General Hospital 1970 1976 Four of the children were from the city of Malmö (250 000 inhabitants) while the remaining 3 were referred to us from other hospitals in the area (with about 1 1/2 million inhabitants) The youngest patient was 12 months old at clinical onset and the next youngest was 14 months Two patients were 2 years 4 months and 7 years 6 months respectively Three patients were around 7 years The mean age was 4 years 10 months The clinical and laboratory findings in the patients are presented in Table 1

METHODS

Dialysis treatment Disposable dialysers with a total surface of 0 16–0 3 m² were used for hemodialysis The connecting tubes and the dialyser which had a total volume of less than 170 ml were primed with fresh blood because of the anemia and thrombocytopenia Each unit of blood (450 ml) contained 500–1 000 I U heparin The duration of each hemodialysis was 2–4 hours As a rule treatment was given every day during the period of oliguria anuria The degree of ultrafiltration was varied according to the desired weight loss during the hemodialysis treatment

Cannulation The silastic teflon arteriovenous cannula system described by Quinton et al (25) was placed in the radial artery and in the cephalic vein In one patient the brachial artery was cannulated instead

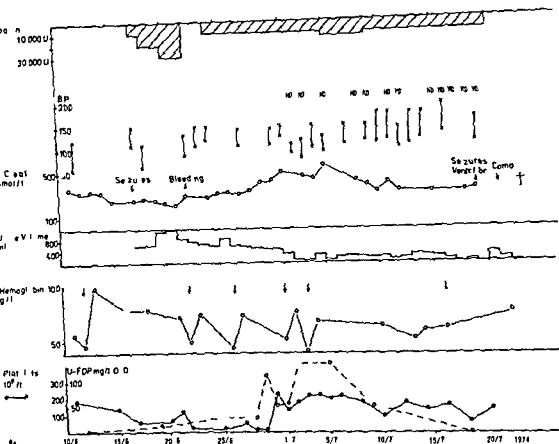

Fig 1 A 7 year old girl with HUS She was first treated with hydrocortisone and prednisolone (100 mg daily) be tween the 13th and 17th of June *On the 17th of June she* got seizures the blood pressure was *150/100 and the* corticosteroids were withdrawn She then *received full* dosage heparin for 2 weeks During this period serum *creatinine rose* urinary output fell successively and severe hypertension appeared Hemodialysis was started on the 3rd week Despite daily HD and intensive anti hypertensive therapy the blood pressure could not be *controlled* and she died from intracranial hemorrhage

sure was raised Treatment with full dosage heparin was started but the urine output nevertheless fell progressively and the serum creatinine gradually increased The platelet count decreased and urinary fibrinogen/fibrin degradation products (FDP) appeared Hemodialysis was started on the 22nd day after onset Intensive therapy because of severe hypertension was given with various combina tions of hydralazine chlorpromazine clonidine reserpine propranolol and trimetha phan (Arfonad) Treatment was not success ful and the child died from an intracranial hemorrhage Autopsy showed hyperplastic in timal thickening with markedly narrowed lumina of renal afferent arterioles and small ar teries Scattered subendothelial deposits of fibrinoid were present but nowhere were fibrin or platelet thrombi found There was widespread glomerular damage with patchy necrosis endothelial cell proliferation and in crease of mesangial matrix The tubuli were dilated and contained proteinaceous and blood cell casts The histological changes were con fined to the kidneys There was a hematoma in the chorioid plexus of the 4th ventricle and diffuse subarachnoidal hemorrhage but no vascular abnormalities in the CNS were found

Some complications in the 7 patients could be ascribed at least partly to the treatment

Parenteral nutrition During the acute stage all patients had an indwelling intravenous catheter by which sugar solutions (10% Invertos) and essential amino acids (Kidnamin Vamin) could be given when necessary Many of the patients could be fed by mouth after vomiting had subsided

Heparin treatment Two patients got no heparin except the small amounts received during hemodialysis Four patients received small doses intermittently or continuously between the dialyses (50–100 I U /kg/24 h) mainly to prevent clotting in the Scribner shunt The dosage was such that the whole blood clotting time and the activated partial thromboplastin time were generally not affected Only one patient was fully heparinised (APTT 80–120 sec)

Blood transfusions Fresh blood was given in association with the dialysis treatment and packed red cells between the treatments when the hemoglobin fell below 60 g/l

RESULTS

The details of the treatment are summarised in Table 2 Six patients were treated with hemodialysis within 5 days of the appearance of signs of hemolytic anemia thrombocytopenia or renal failure The patients received dialysis on 5–8 occasions The maximal duration of anuria was 10 days Two of these patients got no heparin at all between the dialyses and 4 received only small amounts not enough to affect the clotting time or the APT time All 6 patients survived Four of them initially had hypertension which was controlled either by dialysis alone or combined with dihydralazine and reserpine

One of the 7 patients died (Table 2) from intracranial hemorrhage The clinical course is illustrated in Fig 1 A 7 year old girl fell ill with vomiting and diarrhea She soon developed profound anemia hepatomegaly and jaundice Serum creatinine was increased but she had no oliguria in the beginning One week after onset she was referred to our hospital because of convulsions The blood pres

Table 2 *Treatment*

No of patients	Time before first dialysis	No of dialyses	Heparin treatment	No of blood transfusions	Duration of anuria/oliguria
6	<5 days	5–8	None or low dose	3–9	5–10 days
1 †	22 days	12	500–1 500 IU/ kg/24 h	3	27 days

severely damaged Urinary FDP which form on lysis of fibrin deposits in the kidneys appeared late in this patient which might indicate that she had had a weak fibrinolytic defence Although neither fibrin nor platelet thrombi could be found at autopsy 3 weeks later she might not have been able to break down the arteriolar and glomerular thrombi quickly enough In patients like this i e in whom the fibrinolytic capacity is not sufficient to cope with the stress imposed upon it the prognosis may be gloomy However we have so far refrained from thrombolytic treatment because of the serious bleeding complications reported (23)

The etiology of HUS is unknown The search for environmental factors has generally been unrewarding One of our cases showed a significant rise in titre of complement fixing antibodies against Mycoplasma pneumoniae but in none of the others could we detect any clue to the etiology The complement factors were determined in 3 patients C3 was decreased in 2 C4 in 1 and C1q in 1 This suggests that in some cases the initial vessel damage might be mediated through complement activation by an antigen antibody reaction But judging also from some recent reports (5 15 21 27) complement activation occurs in only some of the cases Immunofluorescence studies of renal biopsy specimens have often failed to demonstrate immunoglobulins or complement in the glomerular capillaries (8 12 26) The evidence for immunological mechanisms in HUS is thus weak

The final outcome in HUS seems to vary geographically In Argentina HUS has become an important cause of chronic renal disease in children (9) This is not the case in some other regions (28) including Scandinavia One of our patients who had severe hypertension died while all the others recovered with seemingly normal renal function The prognosis thus seems to depend more upon the severity of the hypertension than upon other factors such as the degree of hemolysis or the duration of oliguria anuria

urosepsis after catheterisation of the bladder in 1 case wound sepsis from the site of the Scribner shunt in 1 case and bleeding during heparin treatment in 2 Two patients had sequelae after the cannulation One patient got paresis of the median and ulnar nerves The paresis was mild and at follow up there was practically no disability The second patient developed gangrene of the fourth finger which had to be amputated

When last seen 1–7 years after recovery all 6 surviving patients had normal renal function and blood pressure

DISCUSSION

Early hemodialysis is in our opinion essential for successful management of the hemolytic-uremic syndrome (7) Many patients present with overhydration and hypertension leading to seizures The intensive hemolysis accentuates the tendency to hyperkalemia which is easily controlled by hemodialysis All the 6 patients who were dialysed within 5 days recovered They were all critically ill on admission The vital importance of early dialysis has repeatedly been stressed (13 15) Peritoneal dialysis has often been used but we have found that hemodialysis is advantageous although it sometimes involves technical problems in small children New types of shunts and filters especially designed for small children have reduced these technical difficulties (16 17) We perform hemodialysis practically every day during the period of oliguria anuria Abundant amino acids and carbohydrate can then be given to the patients without any risk of overloading the circulation In this way the catabolic phase can be shortened Furthermore hemodialysis which takes only 2–4 hours at a time permits early mobilisation in the intervals between the dialyses as well as earlier oral feeding We feel that it is essential to keep the patient in a good general condition throughout the treatment to avoid complications such as bacterial sepsis

Hemolytic anemia is always present in the acute stage of HUS The invariable finding of a negative Coombs test and the typical morphologic appearance of the red cells clearly suggest a non immune acquired hemolytic anemia (3) In such a type of anemia the red cells are thought to be injured during their passage through regions of damaged and obstructed small vessels (4) and not because of an immunological mechanism Treatment of the anemia with corticosteroids is thus theoretically not justified Only one of our patients the one who died received a short course of treatment with prednisone Neither have other workers found any practical value of corticosteroids which thus should be avoided (18)

Biopsy and autopsy studies make it likely that the primary lesion in HUS is a swelling of the endothelial cells of renal arterioles and glomerular capillaries (8 12 20 31) with consequent narrowing of the lumen A secondary accumulation of platelets and fibrin forming either occlusive thrombi (6, 9 20) or subendothelial deposits (8 26 31) seems to play an important role in the pathogenetic process The use of heparin to prevent thrombus formation has been advocated but is controversial (10 13 24 28 30) In our study only one patient was fully heparinised but she died It is difficult to imagine that the small doses received by some of the other patients would have affected the outcome Thus in our experience heparin is not indicated in HUS It might even do harm because of bleeding

It is possible that thrombolytic agents (2 23) or platelet aggregation inhibitors (1) would have been better than heparin in the case with a fatal outcome From Fig 1 it is evident that the decrease in the patient s urinary output was preceded by a few days drop in the platelet count The platelet count remained low during the whole phase of deterioration after which it suddenly returned to normal without any other improvement in her condition This might mean that the pathogenetic mechanism of platelet and fibrin deposition ceased at this point but the kidneys had already been too

severely damaged Urinary FDP which form on lysis of fibrin deposits in the kidneys appeared late in this patient which might indicate that she had had a weak fibrinolytic defence Although neither fibrin nor platelet thrombi could be found at autopsy 3 weeks later she might not have been able to break down the arteriolar and glomerular thrombi quickly enough In patients like this i e in whom the fibrinolytic capacity is not sufficient to cope with the stress imposed upon it the prognosis may be gloomy However we have so far refrained from thrombolytic treatment because of the serious bleeding complications reported (23)

The etiology of HUS is unknown The search for environmental factors has generally been unrewarding One of our cases showed a significant rise in titre of complement fixing antibodies against Mycoplasma pneumoniae but in none of the others could we detect any clue to the etiology The complement factors were determined in 3 patients C3 was decreased in 2 C4 in 1 and C1q in 1 This suggests that in some cases the initial vessel damage might be mediated through complement activation by an antigen antibody reaction But judging also from some recent reports (5 15 21 27) complement activation occurs in only some of the cases Immunofluorescence studies of renal biopsy specimens have often failed to demonstrate immunoglobulins or complement in the glomerular capillaries (8 12 26) The evidence for immunological mechanisms in HUS is thus weak

The final outcome in HUS seems to vary geographically In Argentina HUS has become an important cause of chronic renal disease in children (9) This is not the case in some other regions (28) including Scandinavia One of our patients who had severe hypertension died while all the others recovered with seemingly normal renal function The prognosis thus seems to depend more upon the severity of the hypertension than upon other factors such as the degree of hemolysis or the duration of oliguria anuria

LACTOSE AND PROTEIN ABSORPTION FROM BREAST MILK AND COW'S MILK PREPARATIONS AND ITS INFLUENCE ON THE INTESTINAL FLORA

Investigations on two Infants with an Artificial Anus

W HEINE H J ZUNFT W MÜLLER BEUTHOW and F K GRUTTE

From the Department of Metabolic Diseases and Nephrology of the Paediatric Clinic of the Wilhelm Pieck University Rostock and the Department of Microecology of the Central Institute of Nutrition Potsdam Rehbrucke GDR

ABSTRACT Heine W Zunft H J Muller Beuthow W and Grutte F K (Department of Metabolic Diseases and Nephrology of the Paediatric Clinic of the Wilhelm Pieck University Rostock and Department of Microecology of the Central Institute of Nutrition Potsdam Rehbrucke GDR) Lactose and protein absorption from breast milk and cow s milk preparations and its influence on the intestinal flora Acta Paediatr Scand 66 699 1977 — Lactose and protein absorption from breast milk and a cow s milk preparation enriched up to 7% of lactose were studied in two infants with an artificial anus applied in the ascending colon region The concentrations of protein lactose glucose and galactose were measured in the fistula stools In addition the stools were analysed microbiologically There were relatively high concentrations of lactose and its decomposition products and low concentrations of protein and aminonitrogen in the fistula stools when breast milk was fed When the cow s milk formula was applied only traces of lactose but high amounts of protein were measured The microbiological findings are in agreement with the hypothesis that the bacterial flora of the large intestine is influenced by the lactose and protein concentrations in the intestinal content which reach the large intestine

KEY WORDS Mother s milk lactose absorption protein absorption intestinal flora

It is well known that feeding infants exclusively on breast milk has a specific effect on the appearance of the stools as well as on the composition of their microflora when compared with artificial feeding The faeces are characterized by higher bifidobacterial counts usually including a special type and low counts of putrefactive bacteria The reasons for this difference have been intensively studied (4–9 12 13 16 17 18 19) One of the motives for these studies was to create an artificial milk preparation producing the specific effects of breast milk This would be of practical value in view of the better resistance of breast fed babies against infection especially diarrhoea and in view of other advantages of natural infant nutrition and would reduce the severity of iron depletion among infants fed on artificial milk

In 1950 Gyorgy (8) found a type of bifidobacteria which was dependent on breast milk for its growth in vitro Many natural constituents of breast milk especially aminosaccharides have been tested for their ability to produce a bifidogenic intestinal flora but without success (7) An important step was the discovery by Petuely (16) that lactulose enhances the bifidus flora when added to cow milk preparations

Breast milk however does not contain lactulose (8) and the types of bifid organisms in stools of breast fed infants may differ from those in stools of infants fed with lactulose

The specific effects of the lactose and pro-

Fig. pH, soluble protein, total protein. n = number of faeces samples, % = significance level of differences (Student's t-test)

RESULTS

The biochemical parameters of the stool specimens differed markedly between the two feeding systems. Although the KtNa formula was enriched to contain 7% lactose, this sugar was completely absorbed, whereas an equicaloric breast milk diet resulted in stools containing relatively high amounts of lactose (Fig. 1). Glucose and galactose concentrations differed in a similar manner: when breast milk was given, the stools contained higher galactose and glucose concentrations than when obtained during formula feeding. In contrast to these findings, the stools obtained on a breast milk diet had considerably lower α amino nitrogen and protein concentrations (Figs. 1 and 2). The pH values were low during both feeding systems, but they were slightly lower for breast milk than for the cow's milk preparation.

Higher total counts of viable bacteria were found in the fistula stools obtained by formula feeding (Fig. 3). The numbers of all types of bacteria increased: *Escherichia coli*, *Klebsiella*, *Proteus*, *Lactobacillus* and *Enterococcus*, *Bifidobacterium* and *Bacteroides*.

DISCUSSION

This investigation was performed in order to prove the hypothesis that the microbiological and physicochemical properties of faeces obtained on a breast milk diet depend on delayed lactose absorption and on almost complete absorption of protein in the small intestine.

The lactose and protein concentrations in ordinary stools resulting from breast milk and cow's milk diets are very low, since the prolonged passage through and the intensity of the bacterial metabolism in the large bowel will result in more or less complete utilization of these nutrients (3). Hence, to measure the absorption in the small intestinal tract it is necessary to determine the concentrations of these substances before bacterial decomposition takes place, i.e. when the intestinal content passes the ileocaecal valve.

Our results from studying two infants with an artificial anus in the region of the ascending colon support the hypothesis of lactose from breast milk being less well absorbed than that in our cow's milk preparation. Though equal amounts of lactose were given during both feeding regimens, the lactose concentration in the fistula stools was 169 times higher during breast milk feeding than when the cow's milk preparation was applied. Similar results were obtained by Hirata et al. (12) using an intestinal intubation technique which allowed the analysis of samples of the intestinal content obtained from just above the ileocaecal region. They found higher lactose concentrations during breast milk feeding than during feeding with cow's milk preparations, even when these were enriched to contain 15% lactose. Our experiments revealed similar results for glucose and galactose, the prod

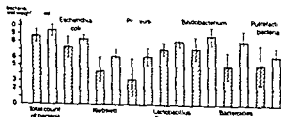

Fig. 3. Microbiological findings in stools from two infants with an artificial anus. The infants were fed either on breast milk (shaded column) or a lactose enriched formula (dotted column). Mean values from 18 faeces samples of the breast milk group and 10 samples of the formula group. Significance level of differences between the two groups in all bacteria with exception of putrefactive bacteria: 99%

tein content the phosphate concentration buffer capacity and other qualities of milk on the intestinal flora are still under discussion (4 6 22) Bullen and coworkers have suggested that the intestinal flora is related to the bio chemical milieu (4*a* 4*b* 22) Grutte Haenel and coworkers suggested that the passage of lactose through the intestinal tract may be con nected with the antiputrifactive action of breast milk (5 6 20) According to their hypo thesis the lactose in cow s milk and its pre parations is completely absorbed This may be due to certain factors for instance phosphate ions promoting the process of mutarotation of β lactose to α lactose the latter being more easily absorbed In breast milk mutarotation is not influenced in this way because of lower concentrations of promoting factors Hence a certain quantity of lactose remains unabsor bed reaches the large intestine and can here be metabolized by the microflora This causes an acid milieu which inhibits putrefactive processes

In view of this hypothesis it would be of interest to compare the absorption of lactose protein and α aminonitrogen from breast milk and from cow s milk preparation in the course of the chyme transport through the small in testinal bowel For this reason lactose and nitrogen balance studies were performed in different feeding regimens on two infants each with an artificial anus provided in the region of the ascending colon as a consequence of in testinal malformations The results obtained were related to the microbiological findings in the stools from the artificial anus (fistula stools)

METHODS

Both infants studied were 4 months old Pregnancy and delivery were uncomplicated Their birth weights were 3280 g and 3060 g respectively Immediately after birth an atresia of the anus was noted in both infants Laparotomy was performed and an artificial anus was applied on the first day of life The further progress of the infants was uneventful Initial feeding on breast milk and later on KiNa formula feeding resulted in an adequate gain in body weight When lactose absorption studies were per formed the general condition of both infants was good and their body weights were about 4 500 g and 4 800 g respectively

For 10 days they were given breast milk at rates of 5×170 ml and 5×160 ml respectively The fistula stools at that time had the typical appearance of stools from breast fed babies The fistula stools were collected every 4 hours over a period of 48 hours The lactose glucose galactose protein and α aminonitrogen concentrations in these stools were determined and microbiological ana lyses were undertaken

The nutrition was then changed to an equicaloric cow s milk formula diet (KiNa) containing 1 8% protein and enriched with lactose up to 7% The actual composition of this formula is given in Table 1 Fourteen days later stool were again examined as described above

Glucose and galactose in stool specimes were deter mined enzymologically according to the method of Berg meyer & Bernt (2) The lactose concentration was cal culated by incubation of stool specimens in phosphate buffer with β galactosidase at pH 7 0 and then measuring the increase in the glucose concentration Protein was controlled according to Lowry (15) α amino-N according to Antener (1) Microbiological investigations were per formed after the methods of Haenel et al (10)

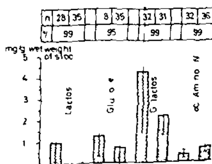

Fig 1 Biochemical findings in stools from two infants with an artificial anus The infants were fed either on breast milk (shaded column) or a lactose-enriched formula (dotted column) (Lactose glucose galactose α amino-N concentration) n=number of faeces samples % = sig nificance level of differences (Student s t test)

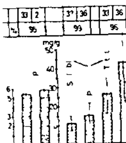

Fig. 2. pH, soluble protein, total protein. n=number of faeces samples. %=significance level of differences (Student t test).

RESULTS

The biochemical parameters of the stool specimens differed markedly between the two feeding systems. Although the KiNa formula was enriched to contain 7% lactose, this sugar was completely absorbed, whereas an equicaloric breast milk diet resulted in stools containing relatively high amounts of lactose (Fig. 1). Glucose and galactose concentrations differed in a similar manner: when breast milk was given, the stools contained higher galactose and glucose concentrations than when obtained during formula feeding. In contrast to these findings, the stools obtained on a breast milk diet had considerably lower α amino nitrogen and protein concentrations (Figs. 1 and 2). The pH values were low during both feeding systems, but they were slightly lower for breast milk than for the cow's milk preparation.

Higher total counts of viable bacteria were found in the fistula stools obtained by formula feeding (Fig. 3). The numbers of all types of bacteria increased: *Escherichia coli*, *Klebsiella*, *Proteus*, *Lactobacillus* and *Enterococci*, *Bifidobacterium* and *Bacteroides*.

DISCUSSION

This investigation was performed in order to prove the hypothesis that the microbiological and physicochemical properties of faeces obtained on a breast milk diet depend on delayed lactose absorption and on almost complete absorption of protein in the small intestine.

The lactose and protein concentrations in ordinary stools resulting from breast milk and cow's milk diets are very low, since the prolonged passage through and the intensity of the bacterial metabolism in the large bowel will result in more or less complete utilization of these nutrients (3). Hence, to measure the absorption in the small intestinal tract it is necessary to determine the concentrations of these substances before bacterial decomposition takes place, i.e. when the intestinal content passes the ileocaecal valve.

Our results from studying two infants with an artificial anus in the region of the ascending colon support the hypothesis of lactose from breast milk being less well absorbed than that in our cow's milk preparation. Though equal amounts of lactose were given during both feeding regimens, the lactose concentration in the fistula stools was 169 times higher during breast milk feeding than when the cow's milk preparation was applied. Similar results were obtained by Hirata et al. (12) using an intestinal intubation technique which allowed the analysis of samples of the intestinal content obtained from just above the ileocaecal region. They found higher lactose concentrations during breast milk feeding than during feeding with cow's milk preparations even when these were enriched to contain 15% lactose. Our experiments revealed similar results for glucose and galactose, the prod

tein content, the phosphate concentration, buffer capacity and other qualities of milk on the intestinal flora are still under discussion (4, 6, 22). Bullen and coworkers have suggested that the intestinal flora is related to the biochemical milieu (4a, 4b, 22). Gruttе, Haenel and coworkers suggested that the passage of lactose through the intestinal tract may be connected with the antiputrifactive action of breast milk (5, 6, 20). According to their hypothesis, the lactose in cow's milk and its preparations is completely absorbed. This may be due to certain factors, for instance phosphate ions, promoting the process of mutarotation of β-lactose to α-lactose, the latter being more easily absorbed. In breast milk, mutarotation is not influenced in this way because of lower concentrations of promoting factors. Hence a certain quantity of lactose remains unabsorbed, reaches the large intestine and can here be metabolized by the microflora. This causes an acid milieu, which inhibits putrefactive processes.

In view of this hypothesis, it would be of interest to compare the absorption of lactose, protein and α-aminonitrogen from breast milk and from cow's milk preparation in the course of the chyme transport through the small intestinal bowel. For this reason, lactose and nitrogen balance studies were performed in different feeding regimens on two infants, each with an artificial anus provided in the region of the ascending colon as a consequence of intestinal malformations. The results obtained were related to the microbiological findings in the stools from the artificial anus (fistula stools).

METHODS

Both infants studied were 4 months old. Pregnancy and delivery were uncomplicated. Their birth weights were 3 280 g and 3 060 g respectively. Immediately after birth an atresia of the anus was noted in both infants. Laparatomy was performed and an artificial anus was applied on the first day of life. The further progress of the infants was uneventful. Initial feeding on breast milk and later on KiNa formula feeding resulted in an adequate gain in body weight. When lactose absorption studies were performed, the general condition of both infants was good and their body weights were about 4 500 g and 4 800 g respectively.

For 10 days they were given breast milk at rates of 5×170 ml and 5×160 ml respectively. The fistula stools at that time had the typical appearance of stools from breast fed babies. The fistula stools were collected every 4 hours over a period of 48 hours. The lactose, glucose, galactose, protein and α-aminonitrogen concentrations in these stools were determined and microbiological analyses were undertaken.

The nutrition was then changed to an equicaloric cow's milk formula diet (KiNa) containing 1.8% protein and enriched with lactose up to 7%. The actual composition of this formula is given in Table 1. Fourteen days later stools were again examined as described above.

Glucose and galactose in stool specimens were determined enzymologically according to the method of Bergmeyer & Bernt (2). The lactose concentration was calculated by incubation of stool specimens in phosphate buffer with β-galactosidase at pH 7.0 and then measuring the increase in the glucose concentration. Protein was controlled according to Lowry (15), α-amino N according to Antener (1). Microbiological investigations were performed after the methods of Haenel et al. (10).

ucts of lactose decomposition there were considerably higher concentrations in the fistula stools obtained from breast milk than in those obtained after feeding on cow s milk this showing that lactose is also split by bacterial activity

In contrast the concentrations of α amino nitrogen and of soluble and total protein in the fistula stools were nearly twice as high during the cow s milk period than during the breast milk period although the amount of protein given daily in the cow s milk was only 1 25 times larger than that contained in the breast milk diet Similar differences in nitrogen concentrations have already been shown between ordinary stools obtained by breast milk feeding and feeding on cow s milk preparations (11)

The reverse situation of protein and lactose digestion/absorption cannot be explained simply by the more rapid passage through the intestinal tract when breast milk is used for feeding Even if the lactose concentration in cow s milk preparations is increased to 7% and more no anti putrefactive bacterial flora will develop It seems more likely that the degree of mutarotation of lactose and its effect on the digestibility of this sugar is the main factor influencing the absorption of lactose

The differences in the biochemical composition of the intestinal contents reaching the colon is probably the cause of the differences in the microbiological findings The total bacterial counts and the counts for all of the different bacterial groups in the fistula stools were higher during application of the cow s milk preparation than during breast milk feeding The composition of the intestinal flora in infants fed on breast milk as determined in stool cultures and characterized by lower counts for putrefactive bacteria and higher counts for bifidobacteria were not confirmed by the microbiological analysis of the fistula stools This indicates that the typical changes appear during the passage of the intestinal contents through the large bowel A tendency to low putrefactive bacteria counts was however recognizable in the fistula stools (Fig 2) this indicating the major importance of a high lactose—low protein concentration for the suppression of putrefactive germs The preponderance of bifidobacteria on the other hand would appear to be a secondary phenomenon

ANTIBODY PRODUCTION BY THE MAMMARY GLAND IN MOTHERS AFTER ARTIFICIAL ORAL COLONISATION OF THEIR INFANTS WITH A NON PATHOGENIC STRAIN *E COLI* 083

R LODINOVÁ and V JOUJA

From the Research Institute for the Care of Mother and Child Prague Czechoslovakia

ABSTRACT *Lodinova R* and Jouja V (Research Institute for the Care of Mother and Child Prague Czechoslovakia) Antibody production by the mammary gland in mothers after artificial oral colonisation of their infants with a non pathogenic strain *E coli* 083 Acta Paediatr Scand 66 705 1977.—Twenty five breast fed and 25 formula fed infants were colonised by oral administration of a living suspension of *E coli* 083 Twenty breast fed and 13 formula fed infants were followed as controls Specific antibody titres in serum stool filtrates and milk and secretory IgA levels in stool filtrates and milk were determined in samples taken fortnightly from birth until 20 weeks of age The haemagglutinating antibody in serum and milk increased in the colonised groups but in stool filtrates an inhibitory effect of breast milk was demonstrated Secretory IgA levels in stool filtrates were significantly higher in colonised infants and breast fed controls than in bottle fed infants during the period of breast feeding Then levels in the colonised groups remained high but in breast fed controls they decreased to values found in bottle fed controls Artificial colonisation evoked local antibody and secretory IgA responses in the intestine as well as an antibody response in the mother s mammary gland The possible protective effect of those responses is discussed

KEY WORDS *Artificial E coli* colonisation antibody response mammary gland intestine sIgA

Over the past 20 years neonatal morbidity and mortality have rapidly decreased in industrialised countries in spite of the fact that the incidence of breast feeding has markedly decreased This might suggest that artificial food can fully substitute for maternal milk

Recently several reports have shown a changing pattern with an increased incidence of infection caused by gram negative bacteria (6)

Since breast milk antibodies are not absorbed from the intestine their protective role has been doubted (13) According to recent views secretory IgA has been considered to be the dominant immunoglobulin of human milk and other secretions as well as the mediator of local immunity (5 8) Secretory IgA may block adherence of bacteria to the intestinal mucosa and influence intestinal flora by selecting mutants of lower virulence (7) The survival of maternal antibodies in the neonatal gut has been attributed to the intrinsic resistance of secretory IgA to trypsin digestion (11)

The problem of increasing gastrointestinal infection due in many cases to *E coli* strains resistant to most antibiotics has become a general one This has stimulated our attempts to find a method for protecting bottle fed infants in a physiological manner

In the present study the influence of artificial colonisation with the non enteropathogenic *E coli* strain 083 used in our previous

work (9) on local antibody and secretory IgA responses in the intestine and mammary gland was investigated.

MATERIALS AND METHODS

Twenty five breast fed and 25 formula fed infants were colonised by oral administration of the non pathogenic *E. coli* strain 083. A living suspension was prepared from a 24 hr culture containing 5×10^{8} organisms/ml. One ml was given to each child during the first 24 hr after birth and again 3 times a week for four successive weeks. Twenty breast fed and 13 formula fed infants were fol-

lowed as controls. (Informed consent was obtained from the parents.)

Blood and stool samples were taken every fortnight until the 16th week and then in the 20th and 24th weeks of life. In 4 mothers from the control group and 17 mothers from the colonised group milk samples were taken every fortnight during breast feeding. Separate milk samples taken from 10 mothers in the second week after delivery were added to the control group. Stool samples from all mothers and infants were taken before colonisation and every fortnight up to 4–6 months. Smears from the infant's

mouth were taken 4 hours after administration of the suspension of *E coli* once a week for four successive weeks i e during the time of colonisation

Specific antibodies against *E coli* 083 in serum stool filtrates and milk were determined by haemagglutination technique (10) secretory IgA levels in stool filtrates and milk by radial immunodiffusion (7) the presence of *E coli* 083 was detected bacteriologically as described in our previous work (9) Secretory IgA was not tested for specificity

For statistical evaluation the chi square test and the Fisher s test (3) were used

RESULTS

Titres of specific haemagglutinating antibodies against *E coli* 083 in the sera of colonised infants were significantly higher than in the control groups between the 6th to 12th weeks of life i e from the 2nd to 8th weeks after the end of colonisation After that period the titres of all groups did not differ (Fig 1)

In stool filtrates the titres of coproantibodies were higher in colonised bottle fed and breast fed infants between the 2nd to 4th weeks than in controls In colonised bottle fed infants the titres remained significantly higher in the 10th 14th and 20th weeks than in controls in colonised breast fed infants after 4 weeks the titres decreased (Fig 2)

Secretory IgA levels in stool were significantly higher in colonised bottle fed and breast fed infants and in breast fed controls than in the bottle fed control group in the 2nd 4th 6th 8th and 10th weeks Following this levels of secretory IgA in breast fed controls decreased and reached about the same low values found in artificially fed controls In both colonised groups however titres remained higher in the 14th and 20th weeks than in both control groups (Fig 3)

Antibody levels against *E coli* 083 in milk samples from mothers of colonised infants were significantly higher in the 2nd 4th and 8th weeks than in milk from mothers whose infants were not colonised (Fig 4)

Secretory IgA in maternal milk was not influenced by colonisation (Fig 4) *E coli* 083 was repeatedly found in the mouth of colonised infants and in their mothers milk but never in the mothers stools (will be published)

DISCUSSION

The serum antibody response after artificial colonisation was not influenced by breast feeding Rauss et al (12) also showed a systemic response after oral vaccination against dysentery even though the local coproantibody production was higher than in serum

Levels of secretory IgA in colonised formula fed and breast fed infants were high from the first week and remained high over the whole period of investigation However in the breast fed group passive transfer of secretory IgA via maternal milk cannot be distinguished from endogenous production In breast fed controls secretory IgA levels were also high during breast feeding and then decreased rapidly

The ability of the mammary gland to produce specific antibodies has also been shown by Allardyce et al (1) Antibodies increased in serum and colostrum after gastrointestinal infection caused by Salmonella during pregnancy Goldblum et al (4) used the same *E coli* strain as we for artificial colonisation of 3 pregnant women and showed by the plaque technique an appearance of colostral cells producing antibodies against the 0 antigen There was a lack of systemic immune reaction in these patients and a suggestion of a transfer of sensitised cells from the gastrointestinal tract into the mammary gland

In the present study only the infants were colonised Even in this arrangement the mammary gland has shown an antibody response but the mechanism is probably different It is suggested that the antibody producing cells of the mammary gland are stimulated by direct contact with antigen present in the infant s mouth

For protection against gastrointestinal infection artificial colonisation can substitute for the secretory IgA component of maternal milk and increase milk antibody levels

INFLUENCE OF ORAL LYSOZYME ADMINISTRATION ON SERUM IMMUNOGLOBULIN AND INTESTINAL SECRETORY IgA LEVELS IN INFANTS

R LODINOVÁ and V JOUJA

From the Research Institute for the Care of Mother and Child Prague Czechoslovakia

ABSTRACT Lodinova R and Jouja V (Research Institute for the Care of Mother and Child Prague Czechoslovakia) Influence of oral lysozyme administration on serum immunoglobulin and intestinal secretory IgA levels in infants Acta Paediatr Scand 66 709 1977 — The influence of lysozyme feeding on the production of serum immunoglobulins and intestinal secretory IgA was studied in full term and premature infants from birth up to the age six months Serum immunoglobulins were not influenced by lysozyme administration An increase in secretory IgA was found in stool filtrates of full term lysozyme fed infants no secretory IgA was detected in controls In this way lysozyme feeding partly substituted for passive transfer of secretory IgA from maternal milk

KEY WORDS Lysozyme immunoglobulins secretory IgA

The difference in incidence of enteric infections between breast fed and bottle fed infants is well known A protective role of breast milk against enteric infections has been suggested from several observations (3 15) The establishment of secretory IgA as the predominant immunoglobulin in milk (10) offered new evidence on the protective role and importance of breast feeding

Another breast milk component—lysozyme—has also been detected in plasma saliva and tears (6 1) This enzyme is known to possess several biological activities closely connected with mechanisms protecting the organism against infection (5) Low levels found in small for date newborns may be partly responsible for their increased susceptibility to infection (11)

In breast milk the level of lysozyme is about mg/ml It modifies the digestive function of breast fed infants influences the character of their faeces and together with Bifidus factor promotes growth of *Lactobacillus bifidus* and inhibits that of *E coli* (5)

Thus bottle fed infants lack two important components of breast milk secretory IgA and lysozyme We have previously demonstrated that oral colonisation with a non enteropathogenic *E coli* strain evoked earlier and higher serum antibody and coproantibody responses as well as secretory IgA production in the intestine of artificially fed infants than in controls (13 14) In the present work we have studied the influence of lysozyme feeding on the production of serum immunoglobulins and secretory IgA in the intestine of artificially fed full term and premature infants as compared with control groups

MATERIALS AND METHODS

All infants under long term investigation were kept in the Department for healthy infants of our Institute from birth until the age of six months Informed consent was obtained from each parent or guardian concerning the

INFLUENCE OF ORAL LYSOZYME ADMINISTRATION ON SERUM IMMUNOGLOBULIN AND INTESTINAL SECRETORY IgA LEVELS IN INFANTS

R LODINOVÁ and V JOUJA

From the Research Institute for the Care of Mother and Child Prague Czechoslovakia

ABSTRACT Lodinová R and Jouja V (Research Institute for the Care of Mother and Child Prague Czechoslovakia) Influence of oral lysozyme administration on serum immunoglobulin and intestinal secretory IgA levels in infants Acta Paediatr Scand 66 709 1977.—The influence of lysozyme feeding on the production of serum immunoglobulins and intestinal secretory IgA was studied in full term and premature infants from birth up to the age six months Serum immunoglobulins were not influenced by lysozyme administration An increase in secretory IgA was found in stool filtrates of full term lysozyme fed infants no secretory IgA was detected in controls In this way lysozyme feeding partly substituted for passive transfer of secretory IgA from maternal milk

KEY WORDS Lysozyme immunoglobulins secretory IgA

The difference in incidence of enteric infections between breast fed and bottle fed infants is well known A protective role of breast milk against enteric infections has been suggested from several observations (3 15) The establishment of secretory IgA as the predominant immunoglobulin in milk (10) offered new evidence on the protective role and importance of breast feeding

Another breast milk component—lysozyme—has also been detected in plasma saliva and tears (6 1) This enzyme is known to possess several biological activities closely connected with mechanisms protecting the organism against infection (5) Low levels found in small for date newborns may be partly responsible for their increased susceptibility to infection (11)

In breast milk the level of lysozyme is about 2 mg/ml It modifies the digestive function of breast fed infants influences the character of their faeces and together with Bifidus factor promotes growth of *Lactobacillus bifidus* and inhibits that of *E coli* (5)

Thus bottle fed infants lack two important components of breast milk secretory IgA and lysozyme We have previously demonstrated that oral colonisation with a non enteropathogenic *E coli* strain evoked earlier and higher serum antibody and coproantibody responses as well as secretory IgA production in the intestine of artificially fed infants than in controls (13 14) In the present work we have studied the influence of lysozyme feeding on the production of serum immunoglobulins and secretory IgA in the intestine of artificially fed full term and premature infants as compared with control groups

MATERIALS AND METHODS

All infants under long term investigation were kept in the Department for healthy infants of our Institute from birth until the age of six months Informed consent was obtained from each parent or guardian concerning the

In breast milk the level of lysozyme is about 2 mg/ml It modifies the digestive function of breast fed infants influences the character of their faeces and together with Bifidus factor promotes growth of *Lactobacillus bifidus* and inhibits that of *E coli* (5)

Thus bottle fed infants lack two important components of breast milk secretory IgA and lysozyme We have previously demonstrated that oral colonisation with a non enteropathogenic *E coli* strain evoked earlier and higher serum antibody and coproantibody responses as well as secretory IgA production in the intestine of artificially fed infants than in controls (13 14) In the present work we have studied the influence of lysozyme feeding on the production of serum immunoglobulins and secretory IgA in the intestine of artificially fed full term and premature infants as compared with control groups

MATERIALS AND METHODS

All infants under long term investigation were kept in the Department for healthy infants of our Institute from birth until the age of six months Informed consent was obtained from each parent or guardian concerning the

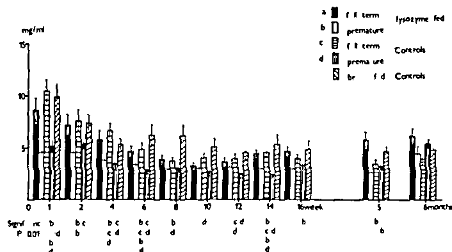

Fig 1 Serum IgG levels in infants

investigation of the infants in accordance with institutional policies A total of 79 infants were divided into five groups 15 full term and 18 premature infants were given egg white lysozyme (10 mg/100 ml of milk formula) from the 1st to the 8th week of age Lysozyme was kindly provided by Società Prodotti Antibiotici Milano Italy (purified crystalline egg white lysozyme in tablets 10 mg each)

13 full term and 13 premature artificially fed infants as well as 20 breast fed infants were followed as controls

Blood and stool samples were taken in the first and second week of life then every fortnight for a period of 16 weeks and finally at ages five and six months All samples were stored on dry ice at −70°C The presence of IgM IgA and IgG in sera and secretory IgA in stool filtrates was first determined qualitatively by a double immunodiffusion technique in a micromodification of the Ouchterlony method using monospecific antisera (IDP set Sevac Prague) The concentration in positive samples was estimated by radial immunodiffusion according to Fahey & Mc Kelvey (4) The coefficient of variance for this method varied between 5 and 8% Lysozyme levels in stool filtrates were estimated by a photometric method (12) Levels of secretory IgA in stool filtrates were statistically evaluated using the chi square test of the 2×2 contingency table For statistical evaluation of serum immunoglobulin levels the one way analysis of variance of log transformed values was used for each interval The mean values of the groups were compared by Scheffe s S method (16) For the SE estimation non transformed data were used

RESULTS

Both groups of full term infants had higher levels of serum IgG than premature infants during the whole period of investigation Serum IgA levels were higher in full term infants from the 12th week there were no dif

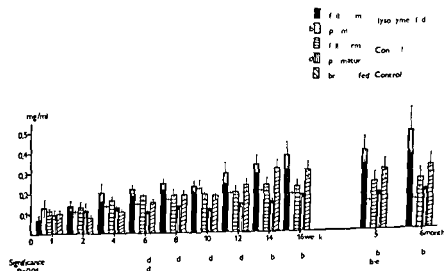

Fig 2 Serum IgM levels in infants

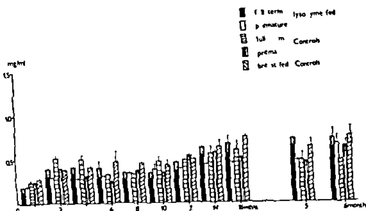

Fig 3 Serum IgA levels in infants

ferences found in IgM levels between full term and premature infants (Figs 1 2 3) Lysozyme administration did not influence serum IgG IgM and IgA levels The influence of lysozyme feeding on the secretory IgA levels in stool filtrites is shown in Table 1 and Fig 4 Lysozyme in stool filtrates from lysozyme fed infants was found only in trace amounts

DISCUSSION

Secretory IgA was influenced by lysozyme feeding in full term artificially fed infants Girard & De Kalbermatten (9) in studies of the antibody activity of human duodenal fluid reported that lysozyme stimulated phago cytosis of IgA and IgM Fubara & Freter (7) suggested a protective effect of secretory IgA which is more resistant to intestinal degrada tion than IgM and IgG derived from serum In the present work secretory IgA was detected in stool filtrates of full term lysozyme fed infants as well as in breast fed ones Fubara & Freter (8) described mechanisms by which intestinal antibodies may be delivered into the lumen of the intestine Their results indicate that an antibody may appear in the intestine as a result of local synthesis or by derivation from a serum antibody Bull et al (2) in a study of human IgA have also shown that IgA from the intestine had properties of 11 S and 7 S IgA On the other hand IgA produced in the intestine was found in the serum In contrast to their findings we could not show an in crease in serum IgA in full term lysozyme fed infants when compared with controls

The explanation of mechanisms of lysozyme

URINARY HYPOXANTHINE XANTHINE AND URIC ACID EXCRETION IN NEWBORN INFANTS WITH PERINATAL COMPLICATIONS

H MANZKE K DÖRNER and J GRUNITZ

From the Department of Paediatrics University Hospital Kiel Federal Republic Germany

ABSTRACT Manzke H Dorner K and Grunitz J (Department of Paediatrics University Hospital Kiel Federal Republic Germany) Urinary Hypoxanthine Xanthine and Uric Acid Excretion in Newborn Infants with Perinatal Complications Acta Paediatr Scand 66 713 1977.—The concentration of hypoxanthine xanthine and uric acid in the first 24-h urine of 105 newborn infants was measured densitometrically by thin layer chromatography 45 of them had moderate or severe perinatal complications Among these newborns 26 infants with perinatal complications (58%) and 4 infants without perinatal complications (7%) had an elevated urinary excretion rate of hypoxanthine Urinary xanthine was not increased uric acid was slightly higher in the group of infants with perinatal complications It seems that a crucial mark is involved if the rate of hypoxanthine exceeds 15% of the total urinary oxypurine excretion or if related to urinary creatinine more than 0 075 µmol hypoxanthine/µmol creatinine Apparently with hypoxic newborns increased values of urinary hypoxanthine excretion can be used to quantify the lack of oxygen retrospectively

KEY WORDS Newborn infants perinatal complications urinary oxypurine excretion

During the first days of life the catabolism of purines is increased in newborn infants This leads to an overproduction of uric acid (9) in particular in premature infants with respiratory disorders (10) Moreover the reabsorption of uric acid by the renal tubular cells seems to be decreased (13) As a result of reduced fluid intake and diminished fluid excretion uric acid often precipitates in the renal tubuli

In newborn infants dying during the first days of life uric acid infarctions can easily be found by post mortem examination of the kidney The analysis of these deposits in the renal tubuli reveals along with uric acid a high percentage of hypoxanthine and xanthine (7)

Stimulated by the studies of Saugstad (11 12) who was the first to report about elevated hypoxanthine concentrations in the blood of hypoxic newborn infants we examined the urinary oxypurine excretion of infants without perinatal complications and those with moderate and severe perinatal complications The aim of the study is to investigate whether urinary purine metabolites may be used to diagnose hypoxia in newborn infants retrospectively

PATIENTS AND METHODS

All infants studied could be divided into three groups

1 Newborn infants without birth complications=infants born by spontaneous delivery with Apgar scores 9 or 10 one min after birth and without attracting attention during their first day of life

2 Newborn infants with moderate birth complications infants born with Apgar scores 5–8 recovering very quickly (Apgar score>8 five min after birth) and being well during the following time

3 Newborn infants with severe birth (perinatal) complications=infants born with Apgar scores 4–8 one min after birth recovering slowly and showing signs of a latent shock or breathing difficulties during the course of their first day of life

Immediately after birth all infants examined were transferred from the delivery room to the Observation Unit of the University Hospital for Obstetrics or to the Intensive Care Unit of the University Hospital for Children Urine was collected during the first 24 hours of life It was en

Table 1 *Secretory IgA levels in stool filtrates*

Groups of infants	No of infants: Total	No of infants: sIgA positive	No of stool samples: sIgA positive	No of stool samples: sIgA negative	No of stool samples: Total	Significance
A Full term lysozyme fed (artificially fed)	15	10	52	113	165	A C $\chi^2=7.83$ $p<0.01$
B Premature lysozyme fed	18	4	5	175	180	A E not significant
C Full term controls (artificially fed)	13	1	3	127	130	A D not significant
D Premature controls	13	1	2	127	129	A B not significant
E Breast fed controls	20	19	75	112	187	E C $\chi^2=21.63$ $p<0.01$

We considered as positive those infants in whome the sIgA was detected at least once in stool filtrates during the whole period of investigation

action still remains unclear It can be suggested that the lysozyme protein molecules have an antigenic effect The lack of antibody response in serum however supports the idea of a local action Lysozyme might exert an enzymatic lysis of bacterial cell wall and their antigenic structures stimulate a local immune response

The fact that artificially fed infants have no secretory IgA and are deprived of sources from maternal milk stimulated our attempts to humanise artificial feeding

reference substance (3 6 8) then hypoxanthine excretion is also higher in infants with birth complications than in those without However the individual values scatter more widely than in the approach underlying Fig 1 A borderline between elevated and non elevated values can be established at 0 075 µmol hypoxanthine/µmol creatinine The mean values ±S D of the urinary hypoxanthine/creatinine excretion for the three groups are as follows infants without birth complications 0 0458±0 0323 infants with moderate birth complications 0 0664±0 0597 infants with severe birth complications 0 1588±0 0882

Due to the wide range of the individual values within the groups a significant difference of the mean values (t test) could only be computed between the infants without birth complications and the infants with severe birth complications ($p<0\ 001$)

Interrelationships between urinary hypoxanthine uric acid creatinine and osmolarity

Fig 2 shows the fairly close relationship between the urinary creatinine and hypoxanthine values ($r=0\ 61$) There was also a positive correlation between the urinary creatinine and osmolarity ($r=0\ 43$ $p<0\ 01$) as well as between the urinary hypoxanthine and osmolarity values ($r=0\ 32$ $p<0\ 05$) However there was neither any significant correlation between the urinary creatinine and the uric acid values ($r=0\ 12$ $p>0\ 4$) nor between the osmolarity and the uric acid values ($r=0\ 07$ $p>0\ 5$) These data are from 78 newborn infants who received only 10–20 ml glucose solution per kg body weight during the first day of life

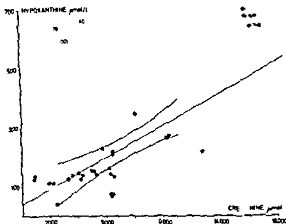

Fig 2 Relationship between urinary hypoxanthine and creatinine excretion in 78 newborn infants during their first day of life

Influence of fluid intake on urinary oxypurine excretion

Next we had to divide our probands into two groups

1 newborn infants who received low fluid supply and

2 newborn infants in particular premature infants who were treated with parenteral infusion of 80–100 ml of glucose solution per kg body weight during the first day of life (and who therefore were passing more urine volume)

Table 1 *Urinary oxypurine excretion as a function of fluid intake in newborn infants during their first day of life*

Urinary output	Newborn infants with low fluid intake (< 0 ml/kg) n = 78	Newborn infants with high fluid intake (>80 ml/kg) n = 3?	t test on mean p
Osmolarity mosmol/l	311±98	187±86	<0 001
Creatinine µmol/l	6 715±4 111	2 160±1 751	<0 001
Total oxypurine µmol/l	2 067±671	2 274±680	>0 1
Hypoxanthine µmol/l	218±181	170±176	<0 001
Uric acid µmol/l	1 800±614	? 116±707	>0 1
Hypoxanthine/creatinine µmol/µmol	0 03 ±0 044	0 056±0 072	<0 01
Uric acid/creatinine µmol/µmol	0 ?68±0 149	0 980±0 404	<0 001

sured that urine collection began no later than 1/2 h after birth

Oxypurine determinations as carried out in this study are based on a modified method reported in a previous paper (2) Evaluations of the thin layer chromatograms were done with a Vitatron TLD densitometer and its integrating recorder UR 402 Hypoxanthine was measured at 254 nm xanthine at 280 nm and uric acid at 293 nm No other oxypurine compounds covered the spots of hypoxanthine xanthine and uric acid as could be shown by treatment of urine samples with xanthinoxydase and uricase Only in some urines a trace of an uv absorbing substance (inosine?) remained within the area of the hypoxanthine The coefficient of variation for the three oxypurines was 5 7% 5 4% and 1 5% (n=12) respectively The addition of 18 2 33 3 and 46 1 ng hypoxanthine or uric acid to 1 ml urine revealed recoveries of 99% 87% and 108% resp 111% 97% and 91% Parallel uric acid determinations carried out with both the densitometric as well as the enzymatic method (Urica quant Biochemica Test Combination Boehringer Mannheim) produced quite similar results (r=0 79 n=42)

The creatinine content of the urine was determined by an autoanalyser method (is yet unpublished) which utilizes dinitroebenzoic acid as the reagent Osmolarity measurements were performed with an osmometer (Knauer Berlin) All analyses were done in duplicate

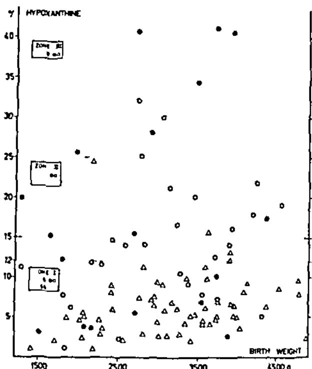

Fig 1 Hypoxanthine rate in the total urinary oxypurine excretion of 105 newborn infants during their first day of life ● infants with severe birth complications ○ infants with moderate birth complications △ infants without birth complications

RESULTS

Proportionality of the urinary oxypurine rates

Urine samples were examined from 105 newborn infants 45 of them had moderate or severe birth complications Fig 1 plots the values of the hypoxanthine rate within the total urinary oxypurine output of all infants As it was difficult to collect the complete 24 h amount of urine the actual amounts of excreted oxypurines could not be determined but only the concentrations within the samples As Fig 1 illustrates the hypoxanthine rates were usually higher in the infants with severe and moderate birth complications than in the newborns without birth complications

In zone I i e with hypoxanthine rates below 12% 19 infants had severe or moderate birth complications and 56 infants had no birth complications

In zone II representing hypoxanthine rates between 12–25% 17 of the 21 infants had birth complications

In zone III representing hypoxanthine rates above 25% all infants had severe or moderate birth complications

Among the infants without birth complications there were only very few that had elevated urinary hypoxanthine rates However a large number of infants with moderate or severe birth complications namely 45% presented normal hypoxanthine rates below 12% There may be two explanations (*a*) the hypoxic state was too short to cause any increased urinary hypoxanthine excretion or (*b*) the 24 h collection time was too long to get information about the hypoxic episode

Furthermore it is unlikely that reduced urine volumes should provide an explanation because the renal clearance of hypoxanthine is much higher than that of uric acid in adults for instance ten times as high (4) In Fig 1 the dividing line for the elevated vs the non elevated hypoxanthine rate within the total urinary oxypurine rate has arbitrarily been set at 15%

If alternatively creatinine is used as the

reference substance (3 6 8) then hypoxanthine excretion is also higher in infants with birth complications than in those without However the individual values scatter more widely than in the approach underlying Fig 1 A borderline between elevated and non elevated values can be established at 0 075 µmol hypoxanthine/µmol creatinine The mean values ±S D of the urinary hypoxanthine/creatinine excretion for the three groups are as follows infants without birth complications 0 0458±0 0323 infants with moderate birth complications 0 0664±0 0597 infants with severe birth complications 0 1588±0 0882

Due to the wide range of the individual values within the groups a significant difference of the mean values (*t* test) could only be computed between the infants without birth complications and the infants with severe birth complications ($p<0.001$)

Interrelationships between urinary hypoxanthine uric acid creatinine and osmolarity

Fig 2 shows the fairly close relationship between the urinary creatinine and hypoxanthine values ($r=0.61$) There was also a positive correlation between the urinary creatinine and osmolarity ($r=0.43$ $p<0.01$) as well as between the urinary hypoxanthine and osmolarity values ($r=0.32$ $p<0.05$) However there was neither any significant correlation between the urinary creatinine and the uric acid values ($r=0.12$ $p>0.4$) nor between the osmolarity and the uric acid values ($r=0.07$ $p>0.5$) These data are from 78 newborn infants who received only 10–20 ml glucose solution per kg body weight during the first day of life

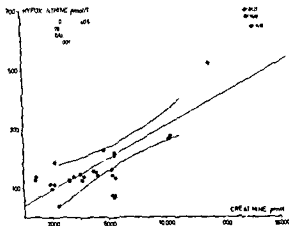

Fig 2 Relationship between urinary hypoxanthine and creatinine excretion in 78 newborn infants during their first day of life

Influence of fluid intake on urinary oxypurine excretion

Next we had to divide our probands into two groups

1 newborn infants who received low fluid supply and

2 newborn infants in particular premature infants who were treated with parenteral infusion of 80–100 ml of glucose solution per kg body weight during the first day of life (and who *therefore* were passing more urine volume)

Table 1 *Urinary oxypurine excretion as a function of fluid intake in newborn infants during their first day of life*

Urinary output	Newborn infants with low fluid intake (<70 ml/kg) $n=78$	Newborn infants with high fluid intake (>80 ml/kg) $n=37$	*t* test on mean *p*
Osmolarity mosmol/l	311±98	187±86	<0 001
Creatinine µmol/l	6 715±4 111	2 160±1 751	<0 001
Total oxypurine µmol/l	[illegible]06 ±671	[illegible] 71±680	>0 1
Hypoxanthine µmol/l	218±181	170±176	<0 001
Uric acid µmol/l	1 800±614	[illegible] 116±707	>0 1
Hypoxanthine/creatinine µmol/µmol	0 037±0 044	0 056±0 077	<0 01
Uric acid/creatinine µmol/µmol	0 [illegible]68±0 149	0 980±0 404	<0 001

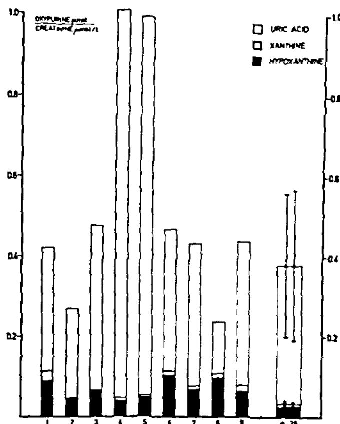

Fig 3 Urinary oxypurine excretion (μmol/μmol creatinine) in 9 newborn infants with severe birth complications during their first day

Table 1 summarizes these two groups the urinary osmolarity was nearly twice as high in the infants with low fluid intake than in the infants with high fluid intake and the creatinine concentration was three times as high in the former than in the latter The total urinary oxypurine concentration however was nearly the same in both groups Correspondingly the hypoxanthine excretion as related to creatinine was approximately a third and the uric acid excretion as related to creatinine 3–4 times lower in infants with low fluid intake than in infants with high fluid intake

Urinary oxypurine excretion and severity of birth complications

The histogram (Fig 3) illustrates the urinary oxypurine excretion as relating to the creatinine in 9 newborn infants with severe birth complications The thin columns represent the individual cases The numerical order of the columns corresponds to the severity of the birth complications the first case being the most severe one All infants had Apgar scores between 4 and 8 one min after birth furthermore complications such as bradycardia of long duration due to coiling of the cord were taken into account In comparison with the control group of 28 newborn infants without birth complications (plotted as a broad column) the hypoxanthine excretion was more than twice their mean value ($\bar{x}$=0 0735±0 0203 resp $\bar{x}$=0 0236±0 0100 μmol/μmol creatinine p<0 001) The excretion of xanthine varies considerably In some infants no xanthine was detectable in their urine The uric acid excretion varies considerably too and no statistical significance could be computed between the two groups ($\bar{x}$=0 4358±0 2712 resp $\bar{x}$=0 3491 ±0 1829 μmol/μmol creatinine p>0 4) There is also no significant difference between the mean values of the total urinary oxypurine excretion between the infants with birth complications and the control group ($\bar{x}$=0 5353± 0 3002 resp $\bar{x}$=0 3800±0 1927 μmol/μmol creatinine p<0 1) All infants compared here received only low fluid supply to exclude the influence of different amounts of fluid intake on the urinary oxypurine excretion

DISCUSSION

Hypoxanthine xanthine and uric acid represent the endproducts of the purine metabolism Under normal conditions more than 90% of the urinary oxypurines are excreted as uric acid (1) and less than 10% as hypoxanthine and xanthine (Fig 4) In newborn infants the hypoxanthine rate amounts to as much as 12% physiologically It seems that a crucial mark is reached if the rate of hypoxanthine exceeds 15% of the total urinary oxypurine excretion or if related to urinary creatinine more than 0 075 μmol hypoxanthine/μmol creatinine Our results confirm indirectly those reported by Saugstad (11 12) who found increased levels of hypoxanthine in the blood of hypoxic newborns

On the other hand clinical experiments with allopurinol an inhibitor of the enzyme xan

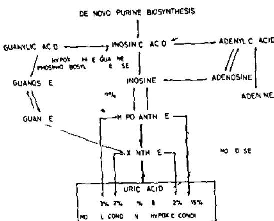

Fig 4 Pathways in purine metabolism and salvage (according to 14)

thinoxydase show that the higher the hy poxanthine concentration in the blood the more hypoxanthine can be recycled to inosinic acid through the action of the enzyme hypo xanthine guanine phosphoribosyl transferase This is called the salvage pathway (14) It may explain why the total urinary oxypurine excre tion in hypoxic newborns is not significantly higher than in normoxic newborns Further more a decreased blood perfusion rate in the kidneys could cause a temporary decrease in the clearance of oxypurines in hypoxic new borns The amount of fluid intake is central for an adequate renal oxypurine excretion dur ing the first days of life (7 10) In utero a good clearance of the placenta for hypoxanthine can be inferred from the positive arterio venous difference in cord blood (5)

After birth renal clearance of hypoxanthine approaches that of creatinine whereas the renal clearance of uric acid is much less (4) In newborn infants with hypoxia of short dur ı tion no significantly elevated urinary oxy purine rates will be found if the urine is col lected during too a long period Otherwise in creased urinary hypoxanthine concentration in newborn infants if measured in the first post natal urine may derive from maternal blood via placenta transfer (5)

Each of these variables must be taken into account if increased values of urinary hy poxanthine excretion are used to quantify the lack of oxygen in hypoxic newborn infants retrospectively

IRON ABSORPTION FROM INFANT MILK FORMULA AND THE OPTIMAL LEVEL OF IRON SUPPLEMENTATION

U M SAARINEN and M A SIIMES

From the Children s Hospital University of Helsinki Finland

ABSTRACT Saarinen U M and Siimes M A (Children s Hospital University of Helsinki Finland) Iron absorption from infant milk formula and the optimal level of iron supplementation Acta Paediatr Scand 66 719 1977.—Thirty healthy infants aged 11–13 months were studied with regard to the iron absorption from proprietary milk formula The infants were divided into three groups (I–III) depending on the concentration of iron in the formula 0 8 (I) 6 8 (II) and 12 8 (III) mg/l respectively The calculated amount of iron absorbed per test dose of 50 ml of milk averaged 5 μg (I) 32 μg (II) and 43 μg (III) Group I differed significantly from groups II and III No correlation was found between iron absorption and hemoglobin MCV serum transferrin saturation or serum ferritin within the range of normal values Our findings suggest that at least 7 mg of iron as ferrous sulphate per litre of formula is required to prevent iron deficiency

KEY WORDS Infant nutrition iron absorption milk

Iron deficiency in infancy remains a common nutritional problem One of the most effective and widespread methods of preventing this deficiency is the use of iron fortified formula Most proprietary formulas contain 10 to 12 mg of iron per litre in the form of ferrous sulphate and this level of fortification is found to be effective in the prevention of the iron deficiency that commonly develops when neonatal iron stores are exhausted after 2 months of age in premature infants and after 4 months of age in term infants (1 2) However a number of recent studies have indicated that even modest degree of iron excess could be harmful to the infant (6 8 17) These considerations raise the question of whether present levels of iron in fortified formula are optimal or whether a smaller amount would be just as effective A salient feature of iron absorption is that the percentage that is absorbed decreases as the dose is increased (4) At the present level of iron fortification of 10 to 12 mg/l an average of about 4% of the iron or 0 4 to 0 5 mg/l is absorbed (14)

This study attempts to find a level of iron supplementation for infant milk formula that would achieve sufficient iron absorption to prevent iron deficiency without unnecessarily high supplementation

MATERIALS AND METHODS

Our study population consisted of 30 infants aged 11 2 to 13 2 months The infants were selected from a group of 250 healthy infants who were followed from birth to one year of age at frequent intervals for dietary instructions and blood sampling In all infants solid foods were introduced late cooked vegetables at 3 5 months cereals at 5 months and meat and eggs at 6 months of age All were initially breast fed and all were weaned prior to the age of 5 months 6 of them to home prepared cow s milk formula which was changed to commercial fresh cow s milk at 6 months of age and 24 of them to an iron supplemented (11 mg Fe/l) proprietary infant milk formula

Iron nutrition was evaluated by the use of hemoglobin RBC indices (a Model S Coulter Counter) serum transferrin saturation (5 13) and serum ferritin (15) (Table I) Because depleted iron stores should markedly influence iron absorption (10 16) two infants with minimal or ex

Table 1 *The infant material*

Geometric mean and the range of the values

hausted storage iron (serum ferritin ≤10 μg/l) were evaluated separately and excluded from the remaining data

Iron absorption studies were performed using radiochemically pure[59] Fe labelled ferrous sulphate (20 mCi/mg New England Nuclear Corporation Boston USA) Precounted doses of 0 8 to 1 0 μCi were mixed with carrier ferrous sulphate in freshly prepared aqueous solution and added to 50 ml of infant milk formula (Tutteli* Valio Oy Helsinki Finland) This milk was given to the infant after 2 hours of fasting followed by an additional hour of fasting Each bottle together with any remaining milk (always less than 5 ml) was counted in order to accurately calculate the ingested volume of formula and dose of isotope The proportion of administered dose retained at 14 days was measured by a whole body counter with four moving detectors at 90° angles

The infants were divided into three study groups each of which received a different concentration of iron in the test milk formula as follows

Group I 0 8 mg/l no ferrous sulphate added

Group II 6 8 mg/l 6 mg of iron as ferrous sulphate added per litre

Group III 12 8 mg/l 12 mg of iron as ferrous sulphate added per litre

All parents were well informed regarding the study and the use of radioactive isotope and participated on a voluntary basis Although we were concerned about the small potential hazard of any use of isotope in infants we felt it could be justified on a one time research basis and using a small number of infants The retained dose of isotope was well within the Scandinavian recommendations on the research use of radioactivity in children namely of magnitude of one year s exposure from natural radiation (12)

RESULTS

The average iron absorption from milk formula was 12% in group I 9% in group II and 7% in group III (Fig 1) The difference between the groups did not reach statistical significance ($p<0\ 10$ between groups I and III) because of the wide range of the values

The calculated amount of iron absorbed per test dose of 50 ml of milk formula averaged 5 μg in group I 32 μg in group II and 43 μg in group III Group I differed significantly from groups II and III ($p<0\ 05$ $p<0\ 001$ respectively) *Although the total quantity of iron absorbed rises with increasing iron concentration* the difference between groups II and III was small and statistically nonsignificant

There was considerable individual variation in iron absorption in each group which did not correlate with the hemoglobin MCV or serum transferrin saturation Surprisingly there was no significant correlation between iron absorption and serum ferritin values within the range of normal serum ferritin values However there was increased absorption in the two infants who were excluded on

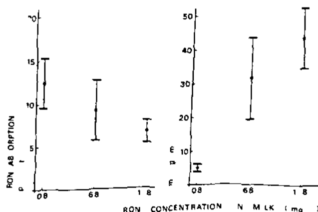

Fig 1 Iron absorption from 50 ml of infant milk formula in % (left) an in μg (right) is correlated with iron concentration in milk The means ± S E M are shown Only the 28 infants with serum ferritin values above 10 μg/l are included

the basis of exhausted iron stores as indicated by serum ferritin ≤10 μg/l The absorption was 49% in one infant in group II and 14% in the other infant in group III an increase of about 5 fold and 2 fold compared to the means of their respective groups

DISCUSSION

Our results indicate that infant milk formula without iron fortification does not meet the requirements of sufficient iron intake (1) On the other hand from our study and from several others it is evident that iron in the form of ferrous sulphate added to infant formulas is absorbed in substantial amounts and is effective in preventing iron deficiency (3 11)

Raising the iron concentration of formula above certain levels results in only minor increases in the total amount of iron absorbed because of a decrease in the percentage absorbed This dose relationship is in accord with previous studies (10) Our findings suggest that at least 7 mg of iron as ferrous sulphate per litre of formula is required to prevent iron deficiency Other data such as those of Gorton & Cross (9) also tend to support this view

It is desirable to use no more fortification than is necessary to prevent iron deficiency The two iron binding proteins of milk lactoferrin and transferrin are normally one third saturated with iron In this condition they show bacteriostatic properties *in vitro* that are lost when the proteins become saturated with iron In milk formulas supplemented with iron these proteins should theoretically become saturated and lose their bacteriostatic properties (6) This might favor the development of enteric infections and alterations in bacterial flora Furthermore iron supplementation in small preterm infants is associated with mild hemolytic states especially in connection with vitamin E deficiency and formulas rich in poly unsaturated fatty acids (8 17) Thus unnecessarily generous iron supplementation should be avoided

Group II 6 8 mg/l 6 mg of iron as ferrous sulphate added per litre

Group III 12 8 mg/l 12 mg of iron as ferrous sulphate added per litre

All parents were well informed regarding the study and the use of radioactive isotope and participated on a voluntary basis Although we were concerned about the small potential hazard of any use of isotope in infants we felt it could be justified on a one time research basis and using a small number of infants The retained dose of isotope was well within the Scandinavian recommendations on the research use of radioactivity in children namely of magnitude of one year s exposure from natural radiation (12)

RESULTS

The average iron absorption from milk formula was 12% in group I 9% in group II and 7% in group III (Fig 1) The difference between the groups did not reach statistical significance ($p<0\ 10$ between groups I and III) because of the wide range of the values

The calculated amount of iron absorbed per test dose of 50 ml of milk formula averaged 5 μg in group I 32 μg in group II and 43 μg in group III Group I differed significantly from groups II and III ($p<0\ 05$ $p<0\ 001$ respectively) Although the total quantity of iron absorbed rises with increasing iron concentration the difference between groups II and III was small and statistically nonsignificant

There was considerable individual variation in iron absorption in each group which did not correlate with the hemoglobin MCV or serum transferrin saturation Surprisingly there was no significant correlation between iron absorption and serum ferritin values within the range of normal serum ferritin values However there was increased absorption in the two infants who were excluded on

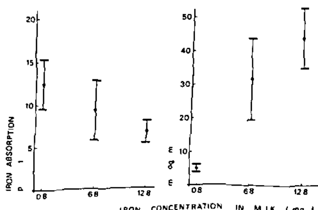

Fig 1 Iron absorption from 50 ml of infant milk formula in % (left) an in μg (right) is correlated with iron concentration in milk The means ± S E M are shown Only the 28 infants with serum ferritin values above 10 μg/l are included

PATIENTS AT A PAEDIATRIC OUT PATIENT CLINIC

A Study with Particular Reference to Psychological and Social Background Factors I The Problem Material Methods and the Actual Visit

R JONSELL

From the Department of Paediatrics University Hospital Umea and the Department of Child and Youth Psychiatry Karolinska Institutet S t Goran s Hospital Stockholm Sweden

ABSTRACT Jonsell R (Department of Paediatrics University Hospital Umeå and Department of Child and Youth Psychiatry Karolinska Institutet S t Coran s Children s Hospital Stockholm Sweden) Patients at a paediatric out patient clinic A study with particular reference to psychological and social background factors I Acta Paediatr Scand 66 723 1977 —A large proportion of the children who attend paediatric clinics present with indefinite somatic symptoms or complaints which are clearly or possibly of a psychological nature At the same time it is known that patients with serious psychological problems tend to seek help far too late This study is an attempt to find out whether the patients who are liable to become problem cases in the long term can be identified by the paediatrician at an early stage and if so in what ways these patients differ from others in a paediatric clientele

All the patients who attended the Paediatric Out Patient Clinic at Umeå Hospital during the course of one year were assessed by the physicians there It was judged that psychological factors of importance were involved in 5 2% that the importance was doubtful in 8 3% and that no psychological factors were involved in 86 5% The proportion of cases involving psychological factors of importance increased with age and amounted to 17% among the 10 to 15 year olds

KEY WORDS Children out patient symptoms psychological

Psychological symptoms and social background are important factors behind the admission of children to hospital (5 29 36) It has also been shown that paediatric wards and out patient clinics offer a large field of work for child psychiatrists (10 11 20 35) The panorama of symptoms which may have a psychological background that the somatic physician often overlooks has been excellently reviewed by Apley & McKeith (4) and described by other authors (1 27 38)

The problem

The number of young people with serious psychological complaints and social maladjustment has become a major problem for the community in Sweden and for many other countries Psychiatrists dealing with children adolescents and adults often meet these patients far too late when their situation has become difficult to influence

Paediatricians and other physicians see many children—as out patients or hospital cases—with symptoms (e g abdominal pains headache poor eating) for which no organic explanation can be found

Main questions initiating this study

If some of the patients who are brought to a paediatrician with symptoms that lack a somatic background are identical with those who much later pose intractable problems for psychiatrists and social authorities? If so can an early diagnosis and adequate measures by

in the tables apply $p \leq 0\ 001$ $p \leq 0\ 01$ $p \leq 0\ 05$ and n s $p > 0\ 05$ where p is the probability of an erroneusly rejected null hypothesis

A note was made from the case records of whether the visit was by appointment the origin of any referral the physicians s measures as well as the diagnosis of symptoms with a four digit ICD code occasionally supplemented in order to describe some symptoms and reasons for a paediatric examination that were not covered by the code Complaints where a psychological cause was probable or suspected were furthermore coded in accordance with a separate list the assessment of what to include being based on the examining physician s opinion as indicated by the case report

RESULTS

The presence of psychological factors at the actual visit was judged by the examining physician as shown in Table 1 The distribution by age is reproduced in Fig 1 The composition of the two groups of subjects and the control group is given in Table 2 A complete set of results has been calculated for the PD group but as they lie in between the results for groups PY and PN they have not been included in the following account About two-thirds of the patients came to the clinic without being referred this was particularly common amongst the youngest children Visits by appointment were 67 2% in PY and 45 8% in PN ($p < 0\ 001$)

The most common diagnoses and symptoms are listed in Table 3 For the most common complaints where a psychological factor was probable or suspected a breakdown by age is given in Fig 2

Table 2 *Composition of subject and control groups*

If a patient had several diagnoses they were all registered If two or more belonged to the same diagnostic group they have been included as a single diagnosis in the table

In some instances it was only after several contacts with the health service that the background to the patient s symptoms became clear The following case report provides an illustration of this

Girl 4 years PD 112

Previous history Two suspected urinary tract infections treated with sulphonamides at another centre

Three weeks before the actual visit emergency visit because of abdominal pains for the previous 24 hours Assessed as constipation given laxatives Urine culture negative Advised to return if symptoms continued

Actual visit Emergency case in the evening Had stayed with relatives for two weeks but on the day of the current visit had returned to her mother where she started to complain of stomach pains urinated frequently and complained that this was painful The pains had ceased when she arrived at the clinic She was found to be alert and unaffected Urine culture negative but in view of the previous history it was planned to admit her for an examination of the urinary tract The mother s history gave no indication of a strained social situation

Subsequent history The patient was admitted as an emergency case two days later because of recurrence of the abdominal pains together with pains on defaecation Nothing abnormal was found at urography and micturition urethrocystography Laboratory tests were normal During her stay on the ward it became clear that her parents had separated six months earlier The father had asked for a divorce while the mother denied any marital discord As the mother worked in the evenings it was considered possible that the girl was insecure in her care An appointment was made to interview both parents

the paediatrician prevent a serious psychiatric or social maldevelopment in certain cases?

Specific questions in this study

1 Can a paediatrician without specialist training in child psychiatry pick out when requested to do so the patients who have non somatic problems that are conditioned by psychological and social conditions?

2 Have these patients previously had particularly frequent contacts with paediatric services in general or for psychological problems in particular and have they been in touch with child psychiatrists?

3 Does the composition of the family or its social and economic conditions contain factors which could involve insecurity for the child? Has the family been in particular need of support from social authorities?

4 Have the parents a high morbidity in general or in particular for certain types of complaints e g mental nervous disorders?

MATERIAL AND METHODS

The material was collected at the paediatric out patient clinic of Umeå in northern Sweden This was the only clinic staffed with paediatricians in a large area with a maximal distance of about 400 km to the clinic For a large part of the population however Umeå was quite close 18 399 *children lived within 40 km of the town* centre and of the other 16 180 children aged 0–15 years the majority had their home within 120 km (26) Families with children with a very low economic standard or poor housing were uncommon (26 31) With regards to the public system for social security in Sweden then economic factors cannot be considered to have had a selective effect upon the persons who attended the paediatric clinic

A referral from a physician was not required in order to attend the paediatric clinic a facility which was utilized above all by parents living in and close to the town In view of the absence of paediatric resources outside the clinic it can be assumed that most cases presenting substantial paediatric problems were remitted or came straight to the paediatric clinic

In the year from 1 July 1970 to 30 June 1971 a record was made of all visits to paediatricians at the Umeå Hospital Patients making an initial visit (defined as one which was not a follow up visit) numbered 4 152 of whom 37 6% had an appointment 34 9% came as emergency cases on Monday–Friday from 8 a m –5 p m and 27 5% were emergency cases outside these hours

Of all the initial visists 86 2% were received by twelve physicians of whom two *had more than 6 years paediatric* experience seven had 3–5 years and three had 1–3 years six of them had at least 6 months experience of child psychiatry The material for the present study was limited to initial visits by children under 16 years of age whose permanent adress lay within the area served by the hospital These limitations left 3 997 initial visits of which 52 9% were boys and 86 9% were living within 40 km from Umeå Distribution by age is shown in Fig 1

At each visit the examining physician judged whether psychological factors had an essential bearing on the child s symptoms using the three alternatives Yes Doubtful and No The term psychological factor is used here in a wide sense i e the fundamental cause might be the child s constitution emotional or social environment or endogenous psychological disorders Two groups of subjects were formed from all the cases which were judged as 1) Psychological Factor Yes (PY) and 2) Psychological Factor Doubtful (PD) In addition a control group was obtained from a sample of the Psychological Factor No (PN) cases matched for the variables sex age and place of residence

Statistical methods

Chi square analyses (in 2×2 contingency tables with Yates correction) mean and median tests and product moment correlations were used (13 14 32 33) The following levels of significance and corresponding symbols

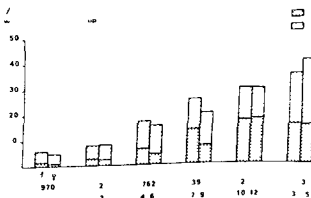

Fig 1 Basic material Proportion of PY and PD cases among the total number of initial visits according to sex and age group Age in completed years

in the tables apply $p \leq 0\ 001$ $p \leq 0\ 01$ $p \leq 0\ 05$ and n s $p > 0\ 05$ where p is the probability of an erroneusly rejected null hypothesis

A note was made from the case records of whether the visit was by appointment the origin of any referral the physicians s measures as well as the diagnosis of symptoms with a four digit ICD code occasionally supplemented in order to describe some symptoms and reasons for a paediatric examination that were not covered by the code Complaints where a psychological cause was probable or suspected were furthermore coded in accordance with a separate list the assessment of what to include being based on the examining physician s opinion as indicated by the case report

RESULTS

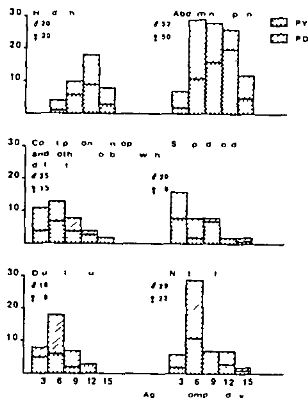

Fig 2 Actual contact Distribution of some common psychogenic complaints (suspected and probable) in different age groups

Other sources The mother had given birth to her first child at the age of 17 This child had been fathered by another man Since that pregnancy the mother had experienced severals periods of back trouble gastritis abdominal pains and psychoneurosis for which she had been registered sick

In 19 7% of the PY group the patients either received a referral to the child psychiatry clinic or were recommended to renew an existing contact or to make use of a referral which had been issued earlier Many parents either declined a proposed referral straight away or else let it lapse even though an appointment had been arranged within a week (Table 4) In such cases the paediatrician often seemed to believe that the patient was being looked after and it was therefore no form of follow up arranged at the paediatric clinic

Cases which were neither followed up at the paediatric clinic nor attended the child psychiatry clinic within two years accounted for 36 3% of the PY group and 43 7% of the PN group (n s)

DISCUSSION

Comparisons with other paediatric clinics are complicated by the lack of detailed statistics for out patient care The predominance of boys and very young children agrees with findings from other studies in the USA and Sweden (7 9 37)

In two separate studies motivated by particular interest in the subject Norstedt (23) (paediatrician in a Stockholm suburb) and Bergfors (6) (paediatric clinic of Skellefteå in northern Sweden) found a proportion of patients attending with psychological and psychosomatic problems at their outpatient clinics that were somewhat higher than the proportion of PY cases in the present study The distribution by age for certain psychogenic complaints in this report is in line with other reports (8 23 39)

A considerable proportion of the patients in the present study presented indefinite somatic symptoms and the frequency of both respiratory infections and other virus infections was relatively high even in the PY group This may reflect a reduced tolerance to the child s symptoms by parents who are under stress for other reasons (21 28) It is also conceivable that the somatic symptoms are used more or less unconsciously as a passport for discussing quite different problems with a physician (22

Table 4 *Number of PY cases where contact with the child psychiatry clinic was proposed or a referral made at the actual contact and subsequent non attendance at the clinic*

	Total (*n*)	Did not attend the child psychiatry clinic within two years (%)
Referral made or contact established in another way	39	25 6
Referral/contact proposed but parents declined	7	–
Paediatrician considered that contact with or referral to child psychiatry clinic was indicated	46	36 9

34 37) Many of the PY cases were left without an active paediatric follow up or a referral elsewhere Other studies have shown that patients who are most in need of help do not return if the initiative for this is left to the parents and the patient (2 19) Since very few parents refuse measures and referral when their children are ill it is surprising how many refuse a referral to a child psychiatrist This attitude which is often reinforced by relatives neighbours etc probably rests on preconceptions about child psychiatry and the concept of psychiatric disorder This fact was indicated in other studies by interviews with parents (12 18 25)

Several studies suggest that many of the patients who are not followed up return to health services later on with the same or other indefinite symptoms (3 15 24 30)

Previous contacts with the health service certain background data and a comprehensive discussion are presented in a second paper (17)

ACKNOWLEDGEMENTS

Financial support to this study was obtained from the Bank of Sweden Tercentenary Fund (project 77/69) and University of Umeå (Ungraduated Researchers Fund)

Other sources. The mother had given birth to her first child at the age of 17. This child had been fathered by another man. Since that pregnancy the mother had experienced severals periods of back trouble, gastritis, abdominal pains and psychoneurosis for which she had been registered sick.

In 19.7% of the PY group the patients either received a referral to the child psychiatry clinic or were recommended to renew an existing contact or to make use of a referral which had been issued earlier. Many parents either declined a proposed referral straight away or else let it lapse, even though an appointment had been arranged within a week (Table 4). In such cases the paediatrician often seemed to believe that the patient was being looked after and it was therefore no form of follow up arranged at the paediatric clinic.

Cases which were neither followed up at the paediatric clinic nor attended the child psychiatry clinic within two years accounted for 36.3% of the PY group and 43.7% of the PN group (n.s.).

DISCUSSION

Comparisons with other paediatric clinics are complicated by the lack of detailed statistics for out-patient care. The predominance of boys and very young children agrees with findings from other studies in the USA and Sweden (7, 9, 37).

In two separate studies motivated by particular interest in the subject, Norstedt (23) (paediatrician in a Stockholm suburb) and Bergfors (6) (paediatric clinic of Skellefteå in northern Sweden) found a proportion of patients attending with psychological and psychosomatic problems at their outpatient clinics that were somewhat higher than the proportion of PY cases in the present study. The distribution by age for certain psychogenic complaints in this report is in line with other reports (8, 23, 39).

A considerable proportion of the patients in the present study presented indefinite somatic symptoms and the frequency of both respiratory infections and other virus infections was relatively high even in the PY group. This may reflect a reduced tolerance to the child's symptoms by parents who are under stress for other reasons (21, 28). It is also conceivable that the somatic symptoms are used more or less unconsciously as a "passport" for discussing quite different problems with a physician (22

PATIENTS AT A PAEDIATRIC OUT PATIENT CLINIC

A Study with Particular Reference to Psychological and Social Background Factors
II Earlier Contacts with the Health Service Social Background Parents Morbidity General Discussion and Recommendations

R JONSELL

From the Department of Paediatrics University Hospital Umeå and the Department of Child and Youth Psychiatry Karolinska Institutet S t Goran s Children s Hospital Stockholm Sweden

ABSTRACT Jonsell R (Department of Paediatrics University Hospital Umeå and Department of Child and Youth Psychiatry S t Goran s Children s Hospital Stockholm Sweden) Patients at a paediatric out patient clinic A study with particular reference to psychological and social background factors II Acta Paediatr Scand 66 729 1977.—Psychological factors were considered by the examining physicians to play an important part in 5 2% of approximately 4000 initial visits to a paediatric clinic These cases are compared with a matched control group representing the cases where the physicians judged that psychological factors were not involved As compared with the controls then a considerably larger proportion of the patients with symptoms associated with psychological factors had a previous history of contacts with child psychiatrists or attendence at the paediatric clinic for problems of a psychological nature Their parents the mothers in particular had a higher frequency of registered sickness for mental nervous disorders and their families had more frequently been the subject of special social inquiries or assistance To a large extent the examining paediatrician was unaware of these background conditions With a better case history and proper follow up one could probably reduce the number of X ray examinations consultations and laboratory tests Further training and better contacts would be facilitated if members of a children s psychiatric team were stationed within the paediatric clinic

KEY WORDS Children out patient psychological social parent morbidity

The material was obtained from a total of 3997 patients who during the course of one year made initial visits to the paediatric clinic in Umeå The material was comprised of 198 cases in which the examining paediatrician judged that psychological factors played a part (the PY group) 300 cases where the importance of psychological factors was doubtful (the PD group) and a matched control group of 544 cases comprising a sample of the cases where psychological factors were judged to be of no importance (the PN group) [1] The questions considered in this paper are chiefly whether these groups differ with respect to the child s earlier contacts with the health service family conditions the parents morbidity and the presence of social problems The purpose of the study and its materials and methods have been described in more detail in the previous paper (15) which also contains data on the children s actual visit to the clinic

PATIENTS AT A PAEDIATRIC OUT PATIENT CLINIC

A Study with Particular Reference to Psychological and Social Background Factors

II Earlier Contacts with the Health Service Social Background Parents Morbidity General Discussion and Recommendations

R JONSELL

From the Department of Paediatrics University Hospital Umeå and the Department of Child and Youth Psychiatry Karolinska Institutet S t Goran s Children s Hospital Stockholm Sweden

ABSTRACT Jonsell R (Department of Paediatrics University Hospital Umeå and Department of Child and Youth Psychiatry S t Goran s Children s Hospital Stockholm Sweden) Patients at a paediatric out patient clinic A study with particular reference to psychological and social background factors II Acta Paediatr Scand 66 729 1977 —Psychological factors were considered by the examining physicians to play an important part in 5 2% of approximately 4000 initial visits to a paediatric clinic These cases are compared with a matched control group representing the cases where the physicians judged that psychological factors were not involved As compared with the controls then a considerably larger proportion of the patients with symptoms associated with psychological factors had a previous history of contacts with child psychiatrists or attendence at the paediatric clinic for problems of a psychological nature Their parents the mothers in particular had a higher frequency of registered sickness for mental nervous disorders and their families had more frequently been the subject of special social inquiries or assistance To a large extent the examining paediatrician was unaware of these background conditions With a better case history and proper follow up one could probably reduce the number of X ray examinations consultations and laboratory tests Further training and better contacts would be facilitated if members of a children s psychiatric team were stationed within the paediatric clinic

KEY WORDS Children out patient psychological social parent morbidity

The material was obtained from a total of 3997 patients who during the course of one year made initial visits to the paediatric clinic in Umeå The material was comprised of 198 cases in which the examining paediatrician judged that psychological factors played a part (the PY group) 300 cases where the importance of psychological factors was doubtful (the PD group) and a matched control group of 544 cases comprising a sample of the cases where psychological factors were judged to be of no importance (the PN group) [1] The questions considered in this paper are chiefly whether these groups differ with respect to the child s earlier contacts with the health service family conditions the parents morbidity and the presence of social problems The purpose of the study and its materials and methods have been described in more detail in the previous paper (15) which also contains data on the children s actual visit to the clinic

Six months before the current visit the school nurse again reported that she had the same discomfort and had fainted during physical training She was referred to the child psychiatry clinic which she visited repeatedly during the next three months She was regarded as being depressed and as not having recovered from her father s death four years earlier There was also trouble with a boyfriend who was abusing alcohol She returned in the same month to the paediatric clinic with the same complaints as be fore—back pain nausea from apples eggs etc One month before the actual visit she attended on account of pain and stiffness in all joints tiredness and an inability to go to school There was still trouble with the boyfriend who had made a suicidal demonstration when she considered breaking off their relationship

Actual visit Arrived as an emergency case having awoken with a dull pain in the epigastrium and blood stained vomit in school Admitted to the ward where she was lively and alert Stomach pains at times which improved with liquid and antacids Laboratory tests provided no evidence of intestinal bleeding Further X rays of the stomach duodenum and lumbar spine showed nothing pathological neither did cholecystography

Subsequent history Returned a month later at night as an emergency referred from a local physician with numbness and paralysis in the legs difficulty in breathing and pains in the chest Clinical examination revealed noth ing pathological She was able to walk afterwards A new contact was arranged with the child psychiatry clinic with which she subsequently kept in touch for a long time

Abdominal pains causing admission to a de partment of surgery (with or without appen dectomy) had been noted in 6 6% of the PY group and in 3 9% of the PN group (n s)

Composition of the family and economic conditions Broken homes due to divorce or death were considerably more common in the PY group (12 6%) than in the PN group (4 6%) ($p<0\ 001$)

Mothers who had been under 20 years old when the patient was born were more com mon in the PY than in the PN group 12 3 and 4 8% respectively ($p<0\ 001$) *This difference* was not only common in the mothers attend ing with young children but even amongst the mothers with children in the older age groups (4–9 years and 10–15 years) *The PF* groups did not differ substantially in the breakdown of all the parents ages at the birth of the child

The PF groups did not differ significantly by the family income occupation or socio economic group (using the H M S O *Classification of Occupations*) (7) The proportion of mothers who were housewives or students (estimated as those with no taxable income) was 31 1% for PY and 35 1% for PN (n s)

Table 2 *Occurrence of the family in social registers in the period 1 1 1966–30 6 1971*

Percentage of PF groups

	PF group		Differ ence
	PY $N=198$	PN $N=544$	PY PN
Child welfare cases	17 6	5 0	
Social welfare cases	18 [illegible]	10 7	
Temperance cases	4 5	[illegible] 2	n s
Entry in social registers in the period 1 1 1970–30 6 1971	[illegible]1 2	11 0	

Parents morbidity The number of parents who had been registered sick for mental nerv ous complaints or disorders at some time dur ing the child s lifetime was significantly higher in the PY than in the PN group This also ap plied to the fathers and mothers separately The differences were marked for the parents of children aged 4–12 years while the fre quencies were similar for those aged 13–15 years (Fig 1)

The mothers in the PY group had a some what larger total number of sick days than those in the PN group while no such differ ence was found for the fathers

Social registers The families in the PY group featured in the social register consider ably more frequently than those in the PN group (Table 2)

Correlations Calculations were made of correlations for all the variables reported with the total material (PY+PD+PN)

The families which had been broken up by divorce or death had an increased incidence of registered sickness for mental nervous dis orders among both the fathers (20 6 against 6 1% $p<0\ 01$) and the mothers (31 8 against 10 1% $p<0\ 001$) and these families were over represented in the social register Families with a record of mental nervous disorders fea tured more frequently in the social register

Table 1 *Previous attendance at and/or admission to child psychiatry and paediatric clinics in Umeå in conjunction with clear or probable psychogenic complaints*

Percentage of PF groups

	PF group		Difference
	PY $N=198$	PN $N=544$	PY PN
Paediatric clinic	28 3	10 5	***
Child psychiatric clinic	16 2	3 1	*

METHOD

A search was made of the hospital in and out patient records on all the children attending at the departments of paediatrics and child psychiatry at Umeå hospital A count was made of earlier paediatric contacts and the case reports were classified by the author into three groups with regard to the importance of psychological factors—Yes Doubtful and No—using the wide definition of psychological factors described in the earlier article The surgical archives were searched and a record was made of the children who had been previously admitted for observation on account of abdominal pains

Data on the composition of the families the parents income occupations and registered sickness were obtained from official records A search was made for data on social investigations or measures over and above the community s normal service

RESULTS

Previous contacts with the health service

The PF groups did not differ statistically in the number of previous initial visits or emergency visits There were however many patients who had made several visits with different symptoms and problems

At previous initial visits or admissions many of the children particularly in the PY group presented problems which were judged to involve psychological factors (Table 1) This was particularly common among the older children

Even though they had a current contact with a child psychiatrist some children came to the paediatric clinic with emergency symptoms that had to be regarded as part of the psychiatric problem This is illustrated by the following case

Girl 15 years PD 313

Earlier history Seen as an emergency case when 14 years old There was a six months history of pains and numbness alternating between the arms and legs For about one week there had been a dull feeling of a lump and pains in the epigastrium She also presented a paresthesia in the right upper arm that did not correspond to the innervation fields *X ray examinations* of the stomach and duodenum were normal

A straightened lumbar lordosis had been found at an earlier X ray examination and she was referred to a physiotherapist for back trouble At a follow up many of the same complaints were noted and as a neurological disorder could not be ruled out she was admitted to the ward Neither *EEG ophthalmologic examination or electrophoresis of CSF* gave any indication of a neurological disorder She was referred to the child psychiatry clinic where it was found that her complaints had disappeared and there seemed to be no need for treatment Some weeks later the school nurse reported that the patient still had numbness headache and stabbing pains in the region of the heart besides subjective discomfort after the lumbar puncture She attended the paediatric clinic and was referred to an orthopedic surgeon who found poor posture and referred her once more to a physiotherapist

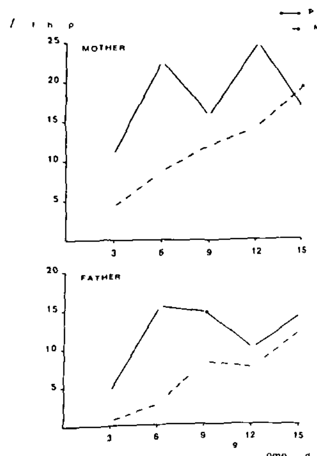

Fig 1 Parents sho had reported sick for mental nervous complaints or disorders during the child s lifetime Percentage of PY and PN groups at different ages of the child in complete years at actual visit

Six months before the current visit the school nurse again reported that she had the same discomfort and had fainted during physical training She was referred to the child psychiatry clinic which she visited repeatedly during the next three months She was regarded as being depressed and as not having recovered from her father's death four years earlier There was also trouble with a boyfriend who was abusing alcohol She returned in the same month to the paediatric clinic with the same complaints as be fore—back pain nausea from apples eggs etc One month before the actual visit she attended on account of pain and stiffness in all joints tiredness and an inability to go to school There was still trouble with the boyfriend who had made a suicidal demonstration when she considered breaking off their relationship

DISCUSSION

The material collected for this study covers practically all the contacts patients have had with paediatricians or child psychiatrists in the area served by the hospital

One can assume that the physician made a note of psychogenic complaints in the paediatric records if he considered them important but there were no doubt problems which escaped detection due to lack of doctor s time the presence of more prominent complaints or lack of contact with the patient This is in accordance with other reports (cf 8 11 17 25) The distribution by marital status parents age income occupation and the proportion of mothers who were housewives agrees with the contemporary study of families with children that was undertaken in Umeå (23)

Several studies have shown that children from broken homes run a greater risk of psychiatric problems and social maladjustment (3 12 22 28) and the relationship between parental deprivation in childhood and psychic disorders in adolescence and adulthood has been pointed out frequently (3 5 26 27) Very young mothers may constitute a risk which is probably due to the fact that their children are mostly unplanned (18) which in turn obstructs educational and occupational plans and impose a cohabitation for which the parents have not planned or are not sufficiently mature If allowance is made for the distribution of the parents by age and sickness benefit class the estimated mean number of sick days per year in the PN group did not differ appreciably from the frequency of registered sickness in the county of Vasterbotten in 1970 (20)

Many investigations have demonstrated a relationship between mental disorders in the parent and behavioural disturbances in their children (1 2 19 21) this also applies to lengthy somatic illness (2 21) Studies starting from children and adolescents with manifest disturbances and maladjustment have likewise shown an increased incidence of mental disorders in the parents (4 10 16 28)

Several investigations have indicated that paediatricians are often consulted for symptoms that may be a reaction to adverse social conditions (10 19) The registered sickness of the parents as a whole and for mental nervous disorders in particular displayed a strong positive correlation with entries in the social register This is in keeping with earlier investigations (13 24)

General discussion and recommendations

The attendance figures and the size of the population served by the hospital suggest that 15–20% of all children aged 0–15 years made one or several initial visits to the paediatric clinic There is thus a large need for help which parents and various bodies interpret as medical It is questionable whether the community s resources for health services and social welfare are correctly structured to meet the real needs of many of these families Studies have pointed out that the somatically inclined paediatrician may neglect to obtain important information about the patient s behaviour and situation information that may be crucial for an understanding of the illness or symptoms (6 17 25) The training of medical students in these matters is poor (8) and during their training they loose a good deal of their original ability to establish contact with parents (11) apparently because the training is excessively concerned with technical aspects

There is always some likelihood that the presenting symptoms have a somatic background and large resources are often invested—in the form of laboratory tests X ray examinations

nd consultations—in ruling out an organic ause These efforts cannot be dismissed in eneral as unnecessary but there are cases as llustrated in the present study which show hat many investigations could be cut down ubstantially if a more thorough history was btained and further personal contact was provided at a second visit Recommendations for better handling of these patients have re cently been suggested by Green (9)

Another advantage would be access to child guidance specialists (psychologist social worker and if possible child psychiatrist) with in the paediatric out patient clinic s own locali ties The patient could then be referred on a simple door to-door basis and the parents would not have to admit that they had been to see[6] psychiatrist In time such an integra tion would eliminate the prejudice against child psychiatry and the continuous contact between paediatric and psychiatric specialists would provide further training on a practical basis as well as further mutual understanding

Although these measures may appear time consuming they would certainly save the health service from many unnecessary new visits (often out of hours when costs are higher) and large investigations Hopefully one could also prevent certain cases from develop ing into serious psychiatric and social prob lems

Efforts should be made to benefit from a situation where the parents experience a need for help for which they attend with the child

ACKNOWLEDGEMENTS

FETAL RISKS DUE TO WARFARIN THERAPY DURING PREGNANCY

KARI O RAIVIO ENSIO IKONEN and SEPPO SAARIKOSKI

From the Children s and Women s Hospital University of Helsinki Helsinki Finland

ABSTRACT Raivio K O Ikonen E and Saarikoski S (Children s and Women s Hospital University of Helsinki Helsinki Finland) Fetal risks due to warfarin therapy during pregnancy Acta Paediatr Scand 66 735 1977 —Two mothers with heart valve prosthesis were treated with warfarin during pregnancy In the first case a caesarean section was done one week after replacement of warfarin with heparin The baby died of cerebral and pulmonary hemorrhage The second mother had a male infant by caesarean section The baby showed warfarin induced embryopathy with nasal hypoplasia and stippled epiphyses (chondrodysplasia punctata) Nasal hypoplasia with or without stippled epiphyses has now been reported in 11 infants born to mothers treated with warfarin during the first trimester and a causal association is probable In view of the risks to both mother and fetus in women with prosthetic cardiac valves it is recommended that therapeutic abortion be advised as the first alternative

KEY WORDS Warfarin embryopathy chondrodysplasia punctata

There is no doubt that pregnancy in a patient with a cardiac valve prosthesis should be discouraged because there are significant risks to both mother and fetus (4 8) When management of the pregnancy without anticoagulation has been attempted maternal complications (cardiac failure and embolization) have been unacceptably frequent and severe (4 17) On the other hand oral anticoagulant therapy with warfarin is definitely associated with an increased rate of abortion and perinatal mortality (4 17 18)

In recent years warfarin has been suspected of having a teratogenic effect (19) Nasal hypoplasia with or without radiologically demonstrable epiphyseal stippling (chondrodysplasia punctata) has been described in at least 10 infants whose mothers had been treated with warfarin during the first trimester of pregnancy

The purpose of this report is to contribute further information relating warfarin administration with chondrodysplasia punctata and to illustrate other risks to mother and fetus in a woman with a cardiac valve prosthesis

CASE REPORTS

Case 1

This case has been briefly described previously (7) The mitral valve of the mother was replaced with a prosthesis 4 mon hs before conception She was maintained on digitalis and warfarin Against medical advice she became pregnant and concealed the fact until the 30th week At that time she was admitted to the hospital because of the cardiac problem and toxaemia of pregnancy (blood pressure 170/120 oedema albuminuria 0 5%) In both respects her condition stabilized thrombotest levels were 15–39 At the beginning of the 35th week oral warfarin was replaced by subcutaneous heparin which was to be continued until term However one week later severe exacerbation of the toxaemia (blood pressure 230/110 low urinary estriol elevated BUN) necessitated termination of the pregnancy by caesarean section

The mother had no postoperative cardiac problems

The male infant weighed 2 160 g at birth and the Apgar score was 7 and 10 at one and seven minutes respectively He had a broad and flat nasal bridge but no other abnormalities Vitamin K (1 mg) was administered

ABSTRACT Raivio K O Ikonen E and Saarikoski S (Children s and Women s Hospital University of Helsinki Helsinki Finland) Fetal risks due to warfarin therapy during pregnancy Acta Paediatr Scand 66 735 1977 —Two mothers with heart valve prosthesis were treated with warfarin during pregnancy In the first case a caesarean section was done one week after replacement of warfarin with heparin The baby died of cerebral and pulmonary hemorrhage The second mother had a male infant by caesarean section The baby showed warfarin induced embryopathy with nasal hypoplasia and stippled epiphyses (chondrodysplasia punctata) Nasal hypoplasia with or without stippled epiphyses has now been reported in 11 infants born to mothers treated with warfarin during the first trimester and a causal association is probable In view of the risks to both mother and fetus in women with prosthetic cardiac valves it is recommended that therapeutic abortion be advised as the first alternative

KEY WORDS Warfarin embryopathy chondrodysplasia punctata

There is no doubt that pregnancy in a patient with a cardiac valve prosthesis should be discouraged because there are significant risks to both mother and fetus (4 8) When management of the pregnancy without anticoagulation has been attempted maternal complications (cardiac failure and embolization) have been unacceptably frequent and severe (4 17) On the other hand oral anticoagulant therapy with warfarin is definitely associated with an increased rate of abortion and perinatal mortality (4 17 18)

In recent years warfarin has been suspected of having a teratogenic effect (19) Nasal hypoplasia with or without radiologically demonstrable epiphyseal stippling (chondrodysplasia punctata) has been described in at least 10 infants whose mothers had been treated with warfarin during the first trimester of pregnancy

The purpose of this report is to contribute further information relating warfarin administration with chondrodysplasia punctata and to illustrate other risks to mother and fetus in a woman with a cardiac valve prosthesis

CASE REPORTS

Case I

This case has been briefly described previously (7) The mitral valve of the mother was replaced with a prosthesis 4 months before conception She was maintained on digitalis and warfarin Against medical advice she became pregnant and concealed the fact until the 30th week At that time she was admitted to the hospital because of the cardiac problem and toxaemia of pregnancy (blood pressure 170/120 oedema albuminuria 0 5%) In both respects her condition stabilized thrombotest levels were 15–39 At the beginning of the 35th week oral warfarin was replaced by subcutaneous heparin which was to be continued until term However one week later severe exacerbation of the toxaemia (blood pressure 230/110 low urinary estriol elevated BUN) necessitated termination of the pregnancy by caesarean section

The mother had no postoperative cardiac problems The male infant weighed 2 160 g at birth and the Apgar score was 7 and 10 at one and seven minutes respectively He had a broad and flat nasal bridge but no other abnormalities Vitamin K (1 mg) was administered

Fig 1 The infant of Case 2 showing nasal hypoplasia and relative shortness of the proximal extremities

Thrombotest was subsequently found to be 19% but clotting and bleeding times were normal The baby did well for 4 hours but then stopped breathing Mechanical ventilation was commenced and had to be continued until death at the age of 3 days 18 hours Autopsy revealed cerebral and pulmonary haemorrhage and septicaemia due to Staphylococcus aureus

Examination of the X rays showed that there was no epiphyseal stippling in the vertebral column or upper extremities but the lower extremities were not studied

Case 2

The mother was 38 years old and had rheumatic heart disease Her calcified mitral valve had been replaced with a prosthesis at the age of 34 years after which she was given continuous warfarin therapy

At the start of the pregnancy three weeks after the last menstrual period the patient had an acute myocardial infarction Recovery was uneventful but because of the possibility of coronary embolism exceptionally low Thrombotest levels (8–13%) were subsequently maintained with warfarin Other medication included digoxin furosemide spironolactone and supplementary potassium

The patient was first seen at the obstetric clinic and the pregnancy was confirmed during the 15th week of gestation She refused therapeutic abortion

Except for a slight degree of polyhydramnios the pregnancy proceeded normally The mother was hospitalized at the 35th week warfarin was discontinued and intravenous heparin started During the 37th week radiographs of the fetus showed marked epiphyseal stippling in the vertebrae proximal and distal humeri and ankle regions On the basis of these findings a prenatal diagnosis of chondrodysplasia punctata was established Uterine contractions started spontaneously at the end of the 37th week but because of signs of asphyxia a caesarean section was performed

After the operation the mother developed septicaemia due to Staphylococcus aureus and was in a critical condition for 4 weeks Complications included left sided hemiplegia presumably due to septic emboli She survived with markedly impaired function in the left arm and leg and some speech impairment

The male infant had a birth weight of 2 150 g a length of 44 cm and a head circumference of 36 cm The Apgar score was 5 and 8 at one and ten minutes respectively The peculiar facial features were immediately noted (Fig 1) The nose was flattened and small the nasal bridge was broad the nares were small but a thin catheter could be passed through both choanae A bilateral simian crease was present but there was no brachydactyly and other malformations were not detected Ophthalmological examination was normal The baby had respiratory difficulties and severe CO_2 retention during the first hours of life but these were relieved by an oropharyngeal airway Vitamin K and fresh frozen plasma were administered during the first day of life and there were no signs of bleeding

Except for the skeletal changes several chest X rays and plain films of the abdomen were all normal The characteristic stippling was seen in and around the vertebral bodies especially the sacrum (Fig 2) in the tarsal and carpal bones and inferior parts of the pelvis and smaller clusters were present in the scapulae proximal and distal humeri and around the femoral heads There were no metaphyseal changes but the humeri and femora were short relative to the radii and tibiae Bone structure and the degree of calcification appeared normal The skull was radiologically normal

Laboratory studies on the first day of life revealed normal serum calcium phosphate and alkaline phosphatase values Urinary amino acid excretion was elevated but the pattern was nonspecific No phosphoethanolamine was detected Urinary hydroxyproline excretion wa 0 096 mmol/day which is below the normal range

After the initial respiratory difficulties and feeding problems the baby did relatively well At the age of 3 weeks tachypnoea and breathing problems reappeared and the baby died at the age of 24 days In addition to the skeletal lesions autopsy revealed diffuse bilateral bronchopneumonia

DISCUSSION

It seems unavoidable that patients requiring anticoagulant treatment will continue to be encountered in antenatal clinics because neither cardiac valve prosthesis (4 17) nor deep ve

Table 1 *Incidence of major clinical features in 11 cases with presumed warfarin induced embryopathy (references 1 9 12–15 17 plus the present Case 2)*

Previous abortions during warfarin therapy	6/11
Pregnancy complications	5/10
Low birth weight (–2 S D or less)	3/11
Mental retardation	3/6
Nasal hypoplasia	11/11
Respiratory difficulties	7/8
Eye abnormalities	4/9
Stippled epiphyses	8/9
Brachydactyly	2/6
Other gross malformations	1/11

nous thrombosis with or without pulmonary embolism (6 18) can be safely managed otherwise

The recommendation to use heparin instead of warfarin during the first trimester and the last weeks of pregnancy appears to be well founded (4 6 8 11) However, in practice this is difficult to follow Women on continuous oral anticoagulation may not recognize or report their pregnancy until late in the first trimester or even later In later pregnancy premature delivery may upset the plans for altering drug treatment as happened in our Case 1

Warfarin has a number of potential harmful effects on the fetus In accord with animal studies (5 10) mothers treated with warfarin have a high incidence of abortions and still births Out of 55 such pregnancies reviewed by Harrison & Roschke (4) 16 (29%) terminated in abortion or stillbirth and there were 4 neonatal deaths Out of the 11 warfarin treated mothers delivering a child with the chondrodysplasia punctata syndrome (Table 1) 6 had a history of previous abortions Our Case 2 had 4 spontaneous abortions during warfarin therapy whereas prior to this treatment she had two normal pregnancies and one therapeutic abortion

The syndrome of nasal hypoplasia with or without stippled epiphyses chondrodysplasia punctata has now been recognized in 11 infants born to warfarin treated mothers (Table 1) Since the nasal deformity is obvious at birth and relatively uncommon it should constitute an indication for careful search for chondrodysplasia punctata

On a clinical radiological and genetic basis Spranger et al (16) have subdivided chondrodysplasia punctata into two main types the Conradi–Hunerman type and the rhizomelic type Affected infants of warfarin treated mothers can be regarded as phenocopies of the former usually dominantly inherited type which clearly is not a homogeneous entity

Our experience with the two cases suggests that the effect of warfarin on the fetus may be dose dependent The thrombotest level in Case 2 was maintained significantly lower than that in Case 1 and her infant exhibited the complete syndrome However as pointed out by Hall (3) the fetal effects of warfarin are difficult to relate to its classical anticoagulant action since clotting factors are not present in first trimester embryos (2)

After the reconstruction of a damaged heart valve the condition of a severely and chronically ill patient improves and she feels optimistic about reproduction However in view of the grave basic heart lesion prospects for long term normal motherhood must be guarded When the fetal risks of abortion malformations and perinatal death are also taken into account we feel that at present a thorough explanation of the problems and unequivocal advice against conception must be given to any woman of childbearing age who is about to undergo valve replacement

THE GROWTH OF THE KIDNEYS IN CHILDREN WITH VESICOURETERIC REFLUX

K KAAS IBSEN P ULDALL and O FRØKJÆR

From University Clinic of Paediatric Children s Hospital Fuglebakken Copenhagen Denmark

ABSTRACT Kaas Ibsen K Uldall P and Frøkjær O (University Clinic of Paediatrics Children s Hospital Fuglebakken Copenhagen Denmark) The growth of the kidneys in children with vesicoureteric reflux Acta Paediatr Scand 66 741 1977.—In a retrospective study 69 kidneys with VUR were divided into 2 groups One group (A) where VUR stopped within 1 year after operation or conservative treatment and a second group (B) where VUR continued for more than 1 year Group A had somewhat more severe grades of reflux than group B The number of infections were practically the same in the two groups The length of the kidneys was measured at the time of diagnosis and compared with the length at the most recent urography after VUR stopped (group A) on average 2 years and 3 months later and with the most recent urography while VUR was still present (group B) on average 1 year and 9 months later It was found that 85% in group A had increased in absolute length while the figure was 60% in group B If the relative growth is calculated (the kidneys length in relationship to L_1-L_3 distance) 60% in group B had decreased while only 30% in group A had decreased

KEY WORDS Children kidney growth vesicoureteric reflux urinary tract infection

The indications for operation for vesico ureteric reflux (VUR) are still under discus sion The purpose of this study is to contribute to the discussion by describing the results found by following the kidneys in one group of patients with persistent VUR for more than one year and in another comparable group where VUR stopped within one year

MATERIAL AND METHODS

From January 1964–December 1974 a total of 76 children were diagnosed as having VUR (173 ureters with reflux) at the Children s Hospital Fuglebakken In the present study a child whose operation for VUR failed a child with stenosis of urethra and children with an insufficient number of urography examinations or where it was impos sible to measure the length of the kidney (30 kidneys) were excluded Further the material was restricted to kidneys of average size (± standard deviations) at the time of diagnosis since abnormal kidneys may be anticipated to behave differently from those of normal size At the time of diagnosis 20 kidneys were not within ±2 standard deviations Of the kidneys being above 2 standard devia tions four had hydronephrosis two duplication of the pelvis three had compensatory growth while in four kidneys no obvious explanation could be found Of the kidneys which were too small all were described as having severe chronic pyelonephritis with one exception Thus the material used in this investigation comprises 69 kidneys with VUR

As the study is retrospective the number of urographies on the patients varied When comparing the lengths of the kidneys the most recent urographies were always used The diagnosis of VUR was made by cystourethrography and all examinations except four were assessed by the same radiologist Each individual patient s urographies were analysed by measuring the length of the kidney and the distance from the upper edge of the first lumbar ver tebra to the lower edge of the third lumbar vertebra

Eklof & Ringertz (?) have drawn up a nomogram in which given the length of the kidney and the distance between L_1-L_3 it is possible to calculate how much a given length of the kidney deviates in standard deviations from an average value The size of the kidneys and the distance from L_1-L_3 were introduced in this nomogram This procedure is found to be approximate as the normal values for the length of the kidneys vary greatly

Table 1 *The age and sex distribution of the material*

Age in years	♀	♂
0–1	10	9
2–3	3	3
4–5	12	2
6–7	5	0
8–9	2	1
10–11	1	1
Total	33	16

RESULTS

The sex and age distribution appears in Table 1

The kidneys were divided into two comparable groups In group A VUR stopped within one year Eleven of these 39 kidneys were treated conservatively with long term antibiotic treatment while the rest were operated upon on average three months after the diagnosis Group B consists of 30 kidneys where VUR continued for more than one year Twelve of these kidneys were subsequently operated upon while the rest were treated with long term antibiotic treatment The duration of reflux from the time of diagnosis until the latest urography used for measuring while reflux was still shown on micturition cystourethrography was 1 year and 9 months on average

In order to compare the two groups some factors which could be expected to influence the growth of the kidneys were registered The grading of reflux is modified after the system described by Rolleston et al (6) This modification (8) was made as more than half of the material would otherwise have been placed in the middle group (moderate reflux) which we found unclearly defined The modified graduation appears in Table 2 It appears that there were more kidneys with severe grades of VUR in group A than group B

The number of infections (more than 10^5 bacteria per ml) during the period from diagnosis until VUR stopped was on an average 2 in group A In group B 2–3 infections were found from the time of diagnosis until the last urography used Further no significant difference was found between the two groups concerning age and sex

Table 3 summarises the growth of the kidneys in the two groups By relative growth is understood the kidney s length is increased in relationship to L_1-L_3 distance By absolute growth is understood an increase in mm On account of uncertain measurement changes of less than 2 mm are described as unaltered size

In group A the urography at the time of diagnosis is compared with the most recent *urography after VUR stopped* (a period of 2 years and 3 months on an average) In group B

Table 2 *The modified graduation and the distribution of the material*

Degree of VUR	(A) Kidneys with VUR for less than one year	(B) Kidneys with persistent VUR for more than one year
I Incomplete filling of the uretero-pelvine system	5	4
II Complete filling without dilatation of the uretero-pelvine system	4	9
III Complete filling and dilatation of the uretero pelvine system	19	13
IV The same as III but with distension of the calyces	11	4
Total	39	30

Table 3 *The growth of the kidneys*

	Group A Kidneys with VUR for less than one year		Group B Kidneys with persistent VUR for more than one year	
	Absolute	Relative	Absolute	Relative
Increased	33 85%	13 33%	20 66 7%	4 13%
Unchanged	? 5%	14 36%	5 16 6%	8 27%
Decreased	4 10%	12 31%	5 16 6%	18 60%
Total	39 100%	39 100%	30 100%	30 100%

the first urography is compared with the most recent urography while VUR is still present (on an average 1 year 9 months later)

As can be seen in Table 3 absolute growth occurred in most of the kidneys in both groups Eighty five percent in group A had increased length while the figure was 60% in group B If the relative growth is calculated 60% in group B had decreased while only 30% in group A had decreased

DISCUSSION

Change in the length of the kidney (maximal length measured from pole to pole on a urography X ray picture) is usually a satisfactory measurement for the complete growth of the kidney This occurs normally at a more or less constant rate from 4–15 years of age The kidneys in each individual have normally the same rate of growth and the difference in length in the two kidneys rarely exceeds 5 mm (3) From his observations on the length of the kidney Hodson (3) made a curve that shows directly the length of the kidney in children 0–16 years of age No significant difference in the size of the kidneys was found between the two sexes

From Hodson s curve and his own measurements Currarino (1) found a constant relationship between the length of the kidney and the distance from the upper edge of the first lumbar vertebra to the lower edge of fourth lumbar vertebra (L_1-L_4 distance) However this does not apply during the first 1–1½ years of life

Eklof & Ringertz (2) have made a very practical nomogram also using the lumbar vertebra as reference to the kidney length This system has been used in this investigation

McLachlan et al (4) found that the length of the kidney in children with VUR is very close to the average length of the kidney stated by Hodson In our material about 80% was of average size

In one of the very few prospective studies Scott & Stansfeld (7) examined a total of 58 patients with VUR who were divided into a group submitted to operation and a control group It was found that the increase in size of the kidney of the operated cases where the reflux was stopped by operation was nearly four times as large as the increase in the control group with persistent reflux Our trial is based on a somewhat different material We have for instance included kidneys where VUR stopped without operation but our results seem however also to support the idea that kidneys with VUR seem to grow less constantly This is especially marked when the relative growth is calculated Our results are reinforced by the fact that in group A more kidneys than in group B belong to the more severe grades of reflux Furthermore the number of infections in the two groups was practically identical

DISCUSSION

Change in the length of the kidney (maxi mal length measured from pole to pole on a urography X ray picture) is usually a satisfactory measurement for the complete growth of the kidney This occurs normally at a more or less constant rate from 4–15 years of age The kidneys in each individual have nor mally the same rate of growth and the differ ence in length in the two kidneys rarely ex ceeds 5 mm (3) From his observations on the length of the kidney Hodson (3) made a curve that shows directly the length of the kidney in children 0–16 years of age No significant dif ference in the size of the kidneys was found between the two sexes

From Hodson s curve and his own meas urements Currarino (1) found a constant rela tionship between the length of the kidney and the distance from the upper edge of the first lumbar vertebra to the lower edge of fourth lumbar vertebra (L_1-L_4 distance) However this does not apply during the first 1–1½ years of life

Eklof & Ringertz (2) have made a very practical nomogram also using the lumbar ver tebra as reference to the kidney length This system has been used in this investigation

McLachlan et al (4) found that the length of the kidney in children with VUR is very close to the average length of the kidney stated by Hodson In our material about 80% was of average size

In one of the very few prospective studies Scott & Stansfeld (7) examined a total of 58 patients with VUR who were divided into a group submitted to operation and a control group It was found that the increase in size of the kidney of the operated cases where the reflux was stopped by operation was nearly four times as large as the increase in the con trol group with persistent reflux Our trial is based on a somewhat different material We have for instance included kidneys where VUR stopped without operation but our re sults seem however also to support the idea that kidneys with VUR seem to grow less constantly This is especially marked when the relative growth is calculated Our results are reinforced by the fact that in group A more kidneys than in group B belong to the more severe grades of reflux Furthermore the number of infections in the two groups was practically identical

Table 1 *The age and sex distribution of the material*

Age in years	♀	♂
0–1	10	9
2–3	3	3
4–5	12	2
6–7	5	0
8–9	2	1
10–11	1	1
Total	33	16

RESULTS

The sex and age distribution appears in Table 1

The kidneys were divided into two comparable groups In group A, VUR stopped within one year Eleven of these 39 kidneys were treated conservatively with long term antibiotic treatment while the rest were operated upon on average three months after the diagnosis Group B consists of 30 kidneys where VUR continued for more than one year Twelve of these kidneys were subsequently operated upon while the rest were treated with long term antibiotic treatment The duration of reflux from the time of diagnosis until the latest urography used for measuring while reflux was still shown on micturition cystourethrography was 1 year and 9 months on average

In order to compare the two groups some factors which could be expected to influence the growth of the kidneys were registered The grading of reflux is modified after the system described by Rolleston et al (6) This modification (8) was made as more than half of the material would otherwise have been placed in the middle group (moderate reflux) which we found unclearly defined The modified graduation appears in Table 2 It appears that there were more kidneys with severe grades of VUR in group A than group B

The number of infections (more than 10^5 bacteria per ml) during the period from *diagnosis until VUR stopped was on an aver*age 2 in group A In group B 2–3 infections were found from the time of diagnosis until the last urography used Further no significant difference was found between the two groups concerning age and sex

Table 3 summarises the growth of the kidneys in the two groups By relative growth is understood the kidney s length is increased in relationship to L_1-L_3 distance By absolute growth is understood an increase in mm On account of uncertain measurement changes of less than 2 mm are described as unaltered size

In group A the urography at the time of diagnosis is compared with the most recent urography after VUR stopped (a period of 2 years and 3 months on an average) In group B

Table 2 *The modified graduation and the distribution of the material*

Degree of VUR	(A) Kidneys with VUR for less than one year	(B) Kidneys with persistent VUR for more than one year
I Incomplete filling of the uretero-pelvine system	5	4
II Complete filling without dilatation of the uretero-pelvine system	4	9
III Complete filling and dilatation of the uretero-pelvine system	19	13
IV The same as III but with distension of the calyces	11	4
Total	39	30

INDICATION OF PRIMARY IMMUNE DEFICIENCY IN FANCONI S ANEMIA

F KARUP PEDERSEN H HERTZ [1] C LUNDSTEEN [2] P PLATZ and M THOMSEN[3]

From the University Clinic of Paediatrics Department G the [1]Section of Teratology Department of Obstetrics and Gynecology and Department of Paediatrics and the [3]Tissue Typing Laboratory Rigshospitalet Copenhagen Denmark

ABSTRACT Pedersen F K Hertz H Lundsteen C Platz P and Thomsen M (University Clinic of Paediatrics Department G Section of Teratology Department of Obstetrics and Gynecology and Department of Paediatrics and Tissue Typing Laboratory Rigshospitalet Copenhagen Denmark) Indication of primary immune deficiency in Fanconi s anemia Acta Paediatr Scand 66 745 1977 —A girl with various congenital malformations developed pancytopenia and hypoplastic bone marrow at the age of 6 years A chromosome study of lymphocytes showed numerous breaks gaps and rearrangements allowing the diagnosis of Fanconi s anemia Treatment with corticosteroids and splenectomy did not result in hematologi remission Repeated immunologic studies showed increasingly deficient T cell function as judged by lymphocyte transformation studies and skin test reactivity whereas T cell number T/B cell ratio immunoglobulins complement factors and neutrophil function were normal A severe Pneumocystis carinii pneumonitis developed but was successfully treated with pentamidine sulfametoxazole with trimetoprim and transfer factor Improvement of T cell function followed transfer factor therapy Combined therapy with corticosteroids and androgens caused partial remission of the hematologic abnormalities The probability of a primary immune deficiency in the patient is discussed

KEY WORDS Fanconi s anemia chromosome aberrations immune deficiency Pneumocystis carinii pneumonitis transfer factor therapy

The designation Faconi s anemia has been used for cases of multiple congenital malformations and bone marrow failure since Fanconi s original report of 3 patients from one family in 1927 (7) Studies from the last 10 years have shown that these patients in addition often have chromosome aberrations such as breaks gaps and rearrangements (5) as well as an increased incidence of malignancies (6)

More than 160 cases familial or sporadic have been published (4) Though frequent infections are part of the symptomatology these have generally been attributed to the neutropenia and reports that include full immunologic work up in patients with typical Fanconi s anemia are not known to us

This report presents a case of typical Fanconi s anemia associated with in vitro T lymphocyte deficiency which clinically manifested itself in a *Pneumocystis carinii* pneumonitis

CASE REPORT

Patient T E a 6-year-old girl was admitted in August 1974 due to recurrent infections of the skin and bleeding tendency of 5 months duration

Three grandparents died of cancer in the stomach rectum and breast respectively A sister of the father died neonatally with severe malformations of unknown kind

48 77°8 6

Previous reports (5 6) have shown that pro nounced VUR must be present to affect the growth of the kidneys severely and to cause progressive renal damage

Even though this undoubtedly is true from our studies the growth of kidneys with persist ent VUR seems to be somewhat slower than of those where VUR stops regardless that the latter group had more severe grades of reflux However, the majority of kidneys with persist ent VUR seems to grow well and it would therefore seem natural to recommend measur ing the kidney growth for instance with a no mogram of Eklof & Ringertz (2) before deci sion is taken whether or not operation should be undertaken

ACKNOWLEDGEMENT

We thank Dr M Eiken for assistance in assessing difficult X rays and Dr K E Petersen for assistance with the manuscript

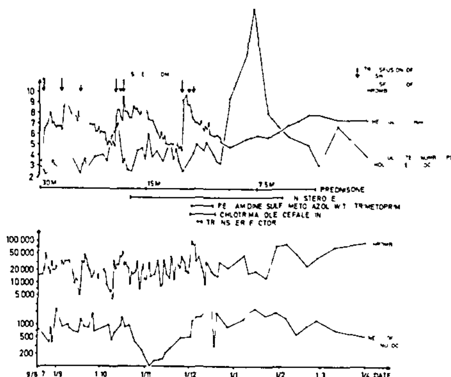

Fig 1 Hematologic paramters in relation to treatment during the period of investigation

and the father himself had pulmonary tuberculosis a decade ago but otherwise cases of congenital malformations severe infections or hematologic diseases were not known to have occurred in the family Two siblings 8 and 2 years old are in good health do not have malformations and both have normal chromosome studies

The pregnancy was normal delivery uncomplicated at the 36th gestational week and birth weight was 2400 g A supernumerary first left finger was removed in the neonatal period and 3 months old the patient underwent surgery for a persistent ductus arteriosus and an aberrant branch of the left pulmonary artery A hearing loss due to atresia of the left external auditory canal and abnormalities of the bony structures of the right middle ear was present Physical development was characterized by height weight and head circumference just below the 10th percentile for age

The patient had uncomplicated chickenpox and measles between the age of 3 and 4 years but never had mumps and in general did not have any increased frequency of infections before the present episode She had never received live vaccines The last 5 months before admission she developed recurrent infections of the skin caused by *Staphylococcus aureus* and *Candida albicans* in addition to bleeding tendency

Physical examination on admission in addition to the above mentioned congenital malformations showed a pale girl with numerous petecchiae and ecchymoses in the skin where also 4 cafe au lait coloured spots were noted There was an oral moniliasis but no other evidence of actual infection Mental development was normal

The following studies were carried out

Hematologic studies On admission hemoglobin concentration was 3 3 mmol/l reticulocytes 0 8% of erythrocytes thrombocytes 15×10^9/l and leucocytes $4\ 8\times10^9$/l A differential count of leucocytes showed 16% neutrophil granulocytes 82% lymphocytes and 2% monocytes Subsequent figures for hemoglobin reticulocytes thrombocytes and neutrophil granulocytes are shown in Fig 1 Erythrocyte mean cell volume was $115\mu^3$ and mean cell hemoglobin concentration 20 mmol/l Serum folate was 24 nmol/l serum B_{12} 888 pmol/l and fetal hemoglobin 21% of total hemoglobin Serum bilirubin and haptoglobin were normal Coombs test was negative and antibodies against leucocytes and thrombocytes were not found

The bone marrow was hypoplastic Erythropoesis initially was of normal intensity later sparse but still normoblastic Myelopoesis was sparse but contained normally structured cells from all stages of development Megakaryocytes were not seen Bone marrow culture did not reveal any colony forming cells and colony stimulating factor in serum could not be demonstrated

Cytogenetic studies Metaphase chromosomes were produced in a standard manner from peripheral blood and stained with orcein or trypsin Leishman One hundred orcein stained and one hundred trypsin Leishman stained mitoses were analysed A total of 73 mitoses (36%) showed aberrations There were 20 mitoses with chromatid gaps 31 with chromatid breaks 5 with chromatid rearrangements 4 with acentric fragments and 13 mitoses showed aberrant distribution of chromosome types within the cell

No dicentrics tricentrics rings endoreduplications or polyploids were seen Using the Latt technique the frequency of sister chromatid exchanges was not found to be increased (12) Fig 2 shows characteristic examples of the aberrations found

Immunologic studies The following in vitro tests were

Fig 2 Characteristic examples of chromosome aberrations found chromatid breaks and gaps (*a*) chromatid rearrangements (*b*) acentric fragment (*c*) and unidentified structure (*d*)

performed repeatedly (*a*) determination of T and B cells in peripheral blood by rosette formation with sheep erythrocytes (E rosettes T cells normal range 5[illegible]–80%) and with complement coated erythrocytes (EAC rosettes B cells normal range 8–[illegible]9%) and by direct membrane immunofluorescence for immunoglobulin bearing cells (Ig+ cells B cells normal range 8–[illegible]8%) (*b*) lymphocyte transformation with the mitogens phytohemagglutinin A (PHA Difco) and poke weed mitogen (PWM Gibco) and the antigens tuberculin (PPD State Serum Institute Copenhagen) Candida albicans (water soluble extract) Staphylococcus aureus and Escherichia coli (both heat

No dicentrics tricentrics rings endoreduplications or polyploids were seen Using the Latt technique the frequency of sister chromatid exchanges was not found to be increased (12) Fig 2 shows characteristic examples of the aberrations found

Immunologic studies The following in vitro tests were

combined therapy with prednisone and anasterone was started. A partial hematologic remission occurred after 9 weeks therapy as manifested by normalization of hemoglobin concentration and stabilisation of thrombocyte particle concentration at a somewhat higher level whereas neutrophil particle concentration remained relatively unchanged.

The patient had a persistent oral moniliasis that could be suppressed by local treatment with nystatin but recurred as soon as the drug was stopped. After 12-13 weeks in the hospital she developed a life threatening interstitial pneumonitis as manifested by fever around 39 degrees Celsius, dry cough, severe tachypnoe, cyanosis, normal lung stetoscopy but diffuse confluent infiltration in both lung fields on chest X ray. Therapy with sulfametoxazole with trimetoprim, cefalexin, clotrimazole and pentamidine aiming at bacterial as well as fungal and Pneumocystis carinii etiology was initiated. Cultures from tracheal aspirates however were and remained negative for bacteria and fungi and repeated serologic studies gave no evidence of viral infection. Microscopic examination of tracheal aspirate in Gomori's methenamine stain showed as seen in Fig. 4 accumulation of foam like material containing cysts of approximately 2 μ s size with a black coloured outer membrane and a dark staining central core allowing the diagnosis of Pneumocystis carinii infection. In an effort to improve T cell function transfer factor prepared from a pool from normal donors was given on 3 consecutive days in doses of 1, ?, and 3 ampouls respectively, each ampoul containing transfer factor corresponding to 0.3×10^9 leucocytes. On completion of transfer factor therapy, when sulfametoxazole with trimetoprim 50 mg/kg/24 h and pentamidine 4 mg/kg/24 h had been given for 6 days, temperature returned to normal. Respiratory distress disappeared a few days later and the two drugs could be discontinued after 2 weeks therapy. Though clinically without evidence of pulmonary infection the patient's bilateral pulmonary infiltrates on X ray persisted for approximately one year before complete resolution occurred.

Transfer factor therapy and cessation of antibiotic treatment was followed by improvement in T cell function as seen in Fig. 3 and described above.

DISCUSSION

Supernumerary thumb, congenital heart disease, middle and external ear malformations, growth retardation and cafe au lait spots of the skin all have been reported previously in patients with Fanconi's anemia (4). The chromosome findings described are not specific for this disease and have been seen also in patients with ataxia teleangiectasia, Bloom's syndrome, glutathion reductase deficiency, pernicious anemia and after irradiation (22). Our patient however showed no clinical signs of these conditions and the combination of congenital malformations, bone marrow failure and chromosome aberrations is definite evidence of Fanconi's anemia. A poor response to therapy with corticosteroids alone and splenectomy but occurrence of partial hematologic remission after 2–3 months of combined treatment with corticosteroids and androgens also is characteristic for this disease (18).

Infection with the protozoan *Pneumocystis carinii* typically gives rise to a severe interstitial pneumonitis. The organism is known to cause disease only in patients with impaired immune response and has been reported in premature and malnourished infants below 4 months, in children with congenital immune deficiencies and in patients with acquired immune deficiencies due to malignant disease or massive immunosuppressive therapy as for example after transplantation (23). Treatment with pentamidine isothionate reduces lethality to approximately 30% (13) and recent reports indicate that sulfamethoxazole with trimetoprim also is effective (15).

Pneumocystis carinii infection, recurrent oral moniliasis, skin reactivity and in vitro tests for T cell function point to a deficient cellular immunity in our patient. Whether this represents a primary immune deficiency or is a therapy induced secondary phenomenon is quite complicated to judge.

Corticosteroids may impair the response to skin tests and are also known to influence lymphocyte function. However they affect the PHA response of various subpopulations of lymphocytes differently thus increasing the response of bone marrow lymphocytes and medullary thymus cells but diminishing that of splenic lymphocytes (3) and the resulting effect on transformation of the total lymphocyte population of peripheral blood therefore may be only minor. Splenectomy is known to decrease the response of lymphocytes to transformation with as well mitogens as antigens in the immediate postoperative period but in a recent study the response was

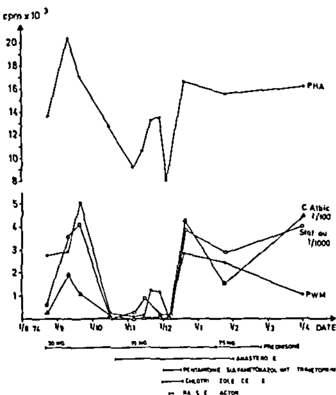

Fig 3 Results of lymphocyte transformation tests using phytohemagglutinin (PHA) and poke weed mitogen (PWM) as mitogens and Candida albicans and Staphylococcus aureus as antigens The lower normal value for stimulation with PHA is 14000 increment counts per minute (cpm) with PWM 3500 and with the antigens 1000 cpm All figures are median values of triplicates

killed organisms) All methods are described in detail elsewhere (20)

Initially normal percentages of E rosettes EAC rosettes and Ig+ cells were found E and EAC rosettes remained within normal range throughout the period of observation with a variation from 66–82% (1 54–6 22×10⁹/l E rosette forming lymphocytes) and 9–24% (0 39–1 63×10⁹/l EAC rosette forming lymphocytes) respectively Ig+ cells on two occasions November 20th and December 3rd however were very low 2% and 1% (0 07 and 0 02×10⁹/l) respectively whereas EAC rosettes on the same dates were 13% and 23% (0 44 and 0 43×10⁹/l)

Fig 3 shows the results obtained from the lymphocyte transformation tests with PHA PWM *Candida albicans* and *Staphylococcus aureus* The response to *Escherichia coli* followed that to *Staphylococcus aureus* and the response to PPD was negative It is seen that the results fall in three parts At the first 3 investigations in August and September normal to borderline transformation was found From the middle of October to the beginning of December that means before any clinical evidence of infection was present the response to mitogens as well as to antigens was severely depressed After treatment with transfer factor pentamidine and antibiotics as described below lymphocytes showed a normal transformation response to PHA and antigens but the response to PWM remained subnormal

The concentration of immunoglobulins in serum was normal IgG 14 5 g/l IgA 1 19 g/l IgM 0 64 g/l and IgE 100 μg/l Also the concentration of adenosine deaminase in erythrocytes was normal

Unstimulated and stimulated nitro blue tetrazolium test (NBT test) were normal and the same was true of granulocyte myeloperoxidase In vitro examination of neutrophil capability of uptake and intracellular killing of *Staphylococcus aureus* showed no signs of significant primary defect in neutrophil function (14)

Concentration of complement factors C_{1q} C_{1s} C_3 proactivator C_3 C_4 and C_5 and total hemolytic complement in serum all were normal (16 17)

Skin tests performed during the 3rd week after initiation of prednisone therapy with PPD streptokinase/streptodornase and Candida albicans antigen in dilution 1 1000 and 1 100 were negative whereas Candida albicans antigen in dilution 1 10 caused a positive reaction with a skin infiltration of 16 mm in diameter Sensitization with 0 05 ml 10% solution of 2 4-dinitrochlorobenzene in acetone applied to the forearm on a filter paper 1 cm in diameter for 12 hours was not followed by reaction on challenge with a similar 0 1% solution applied in the same manner 16 days later

Other studies Initially cultures from nose and throat trachea blood urine and stools were negative for pathogenic bacteria but *Candida albicans* was grown from the throat Virus could not be cultured from throat washings or stools by routine methods Antibody titers against Influenza virus A B and C Adeno virus Respiratory syncytial virus Herpes simplex virus Parotitis virus Mycoplasma and Ornithose agent did not give any evidence of recent or actual infection and hepatitis associated antigen was not found Morbilli virus complement fixation titer was positive in the dilution 1 32

Chest X ray skull X ray and an intravenous pyelogram were normal

As seen from Fig 1 prednisone alone in doses of 2 mg/kg/24 h and splenectomy did not affect the pancytopenia and on the basis of a diagnosis of Fanconi s anemia

Fig 4 Pneumocystis carinii cysts in tracheal aspirate Gomori s methenamine stain original magnification ×100

combined therapy with prednisone and anasterone was started A partial hematologic remission occurred after 9 weeks therapy as manifested by normalization of hemoglobin concentration and stabilisation of thrombocyte particle concentration at a somewhat higher level whereas neutrophil particle concentration remained relatively unchanged

The patient had a persistent oral moniliasis that could be suppressed by local treatment with nystatin but recurred as soon as the drug was stopped After 12–13 weeks in the hospital she developed a life threatening interstitial pneumonitis as manifested by fever around 39 degrees Celsius dry cough severe tachypnoe cyanosis normal lung stetoscopy but diffuse confluent infiltration in both lung fields on chest X ray Therapy with sulfametoxazole with trimetoprim cefalexin clotrimazole and pentamidine aiming at bacterial as well as fungal and Pneumocystis carinii etiology was initiated Cultures from tracheal aspirates however were and remained negative for bacteria and fungi and repeated serologic studies gave no evidence of viral infection Microscopic examination of tracheal aspirate in Gomori s methenamine stain showed as seen in Fig 4 accumulation of foam like material containing cysts of approximately 2 μ s size with a black coloured outer membrane and a dark staining central core allowing the diagnosis of Pneumocystis carinii infection In an effort to improve T cell function transfer factor prepared from a pool from normal donors was given on 3 consecutive days in doses of 1 2 and 3 ampouls respectively each ampoul containing transfer factor corresponding to $0\ 3\times10^9$ leucocytes On completion of transfer factor therapy when sulfametoxazole with trimetoprim 50 mg/kg/24 h and pentamidine 4 mg/kg/24 h had been given for 6 days temperature returned to normal Respiratory distress disappeared a few days later and the two drugs could be discontinued after 2 weeks therapy Though clinically without evidence of pulmonary infection the patient s bilateral pulmonary infiltrates on X ray persisted for approximately one year before complete resolution occurred

Transfer factor therapy and cessation of antibiotic treatment was followed by improvement in T cell function as seen in Fig 3 and described above

DISCUSSION

Supernumerary thumb congenital heart disease middle and external ear malformations growth retardation and cafe au lait spots of the skin all have been reported previously in patients with Fanconi s anemia (4) The chromosome findings described are not specific for this disease and have been seen also in patients with ataxia teleangiectasia Bloom s syndrome glutathion reductase deficiency pernicious anemia and after irradiation (22) Our patient however showed no clinical signs of these conditions and the combination of congenital malformations bone marrow failure and chromosome aberrations is definite evidence of Fanconi s anemia A poor response to therapy with corticosteroids alone and splenectomy but occurrence of partial hematologic remission after 2–3 months of combined treatment with corticosteroids and androgens also is characteristic for this disease (18)

Infection with the protozoan *Pneumocystis carinii* typically gives rise to a severe interstitial pneumonitis The organism is known to cause disease only in patients with impaired immune response and has been reported in premature and malnourished infants below 4 months in children with congenital immune deficiencies and in patients with acquired immune deficiencies due to malignant disease or massive immunosuppressive therapy as for example after transplantation (23) Treatment with pentamidine isothionate reduces lethality to approximately 30% (13) and recent reports indicate that sulfamethoxazole with trimetoprim also is effective (15)

Pneumocystis carinii infection recurrent oral moniliasis skin reactivity and in vitro tests for T cell function point to a deficient cellular immunity in our patient Whether this represents a primary immune deficiency or is a therapy induced secondary phenomenon is quite complicated to judge

Corticosteroids may impair the response to skin tests and are also known to influence lymphocyte function However they affect the PHA response of various subpopulations of lymphocytes differently thus increasing the response of bone marrow lymphocytes and medullary thymus cells but diminishing that of splenic lymphocytes (3) and the resulting effect on transformation of the total lymphocyte population of peripheral blood therefore may be only minor Splenectomy is known to decrease the response of lymphocytes to transformation with as well mitogens as antigens in the immediate postoperative period but in a recent study the response was

found largely normalized 10 days postoperatively (2) In our case the first observed severely depressed lymphocyte transformation study (on October 14th) was made just before splenectomy and furthermore T cell function remained severely depressed quite far beyond the 10th postoperative day Antibiotic therapy that at least in case of sulfametoxazole with trimetoprim may decrease the response of lymphocytes to transformation with PHA (8) had not yet been started when pronounced cellular immune deficiency developed Viral infection which is known to influence cellular immunity in certain instances (24) was not present as judged by clinical examination, virus cultures and serologic studies In conclusion we therefore find that the evidence is in favor of a primary immune deficiency rather than a purely therapy induced immune suppression though the latter cannot be quite excluded The variable degree of depression of T cell function initially may be accounted for if it is assumed that the deficiency of cellular immunity in Fanconi s anemia like the hematologic changes develop gradually at a certain age This would also be in accordance with the fact that our patient had measles and chickenpox without complications in earlier life

On two occasions a discrepancy between EAC rosettes and Ig+ cells were observed Both methods for estimation of B lymphocytes correlate well in our hands in normal individuals but may give different results in patients with immune deficiencies Yata & Tsukimoto (25) in patients with Bruton s agammaglobulinemia found that these patients lack lymphocytes with surface immunoglobulins but have normal frequency of complement C_3 receptor bearing (and thus EAC rosette forming) lymphocytes and suggest that this receptor occurs at an early maturation stage of B lymphocytes Perhaps our findings therefore indicate that B lymphocytes in peripheral blood on these two occasions were immature

Two patients have been reported with familial or congenital pancytopenia and immune deficiency but they did not have congenital malformations or chromosome abnormalities (1 11) and thus did not have typical Fanconi s anemia

Immune deficiency is known to occur also in ataxia teleangiectasia (19) and Blooms syndrome (9) disorders with chromosome aberrations like those found in Fanconi's anemia Furthermore all three categories of patients are known to have an increased incidence of leukemia (22) It is tempting to speculate whether chromosome aberrations and immune deficiency are causally related and whether immune deficiency could possibly constitute the common condition for malignant growth in the three diseases

Transfer factor is a dialyzed leucocyte extract with a molecular weight below 10000 (21) In various situations it has been shown to transfer cellular immunity and thus improve the function of deficient T cells (10) As seen from Fig 3 the transfer factor injections in our patient were actually followed by improved T cell function Pentamidine and antibiotics given concomitantly could well be responsible for the clinical recovery from the pneumonitis Disappearance of postoperative immunosuppressive effects after splenectomy and cessation of antibiotics especially sulfametoxazole with trimetoprim may have played a role in improving T cell function A spontaneous improvement is also possible but the close time relation suggests an unspecific immunostimulating effect of the transfer factor therapy

In summary this report presents evidence of cellular immune deficiency suspected to be primary in a patient with Fanconi s anemia and furthermore suggests an association between transfer factor therapy and improvement of T cell function

ASSESSMENT OF COR PULMONALE IN CYSTIC FIBROSIS BY ECHOCARDIOGRAPHY

E RYSSING

From the Ultrasound Laboratory and the Department of Paediatrics TG Rigshospitalet Copenhagen Denmark

ABSTRACT Ryssing E (Ultrasound Laboratory and Department of Paediatrics TG Rigshospitalet Copenhagen Denmark) Assessment of cor pulmonale in cystic fibrosis by echocardiography Acta Paediatr Scand 66 753 1977—Thirty-one patients with cystic fibrosis of varying severity were examined by echocardiography Right ventricular dimension (RVD) was above upper normal limit in 14 patients and right ventricular dimension index (RVD index) was higher than the upper normal limit in 11 patients Furthermore there was a significant relationship between increasing RVD index and 1) decreasing forced vital capacity (FVC) both actual test results and average 6 months values and 2) decreasing peak-expiratory flow rate (PEFR) both actual test results and average 6 months values This observation suggests a persistent heart involvement Five patients had either heart failure and/or electrocardiographic evidence of right ventricular abnormality These patients had increased RVD index and one patient with the highest RVD index died 8 weeks after the examination The present study has shown the usefulness of echocardiographic measurement of right ventricular dimension and of septal motion in assessing cor pulmonale before development of electrocardiographic abnormalities and right heart failure

KEY WORDS Echocardiography cor pulmonale cystic fibrosis

The purpose of the present investigation has been to study the development of cor pulmonale in cystic fibrosis (CF) by echocardiography There is only one publication on this subject (14)

MATERIAL AND METHODS

The material comprised 31 patients with CF of varying severity whose ages ranged from 4 to 23 years and averaged 1? 8 years None of the patients had previous signs of heart disease

Echocardiographic examinations were done using a Diasonograph NE 410 B with an unfocused 4 5 MHz transducer 10 mm in diameter a storage scope and Polaroid photographing of the screen picture Patients were examined in the supine position with head elevated to about 30° for the patient s comfort and to minimize coughing With the transducer placed along the left sternal border the location was sought which visualized in the best possible way the right ventricular anterior wall septum the posterior mitral valve and the posterior left ventricular wall Right ventricular dimension (RVD) was measured between the right septal surface and the right ventricular epicardium at the end diastole as determined from simultaneous electrocardiogram Because many patients had excessive excursions of the interventricular septum with respiration average values of at least 5 measurements but usually 10 to 12 measurements have been determined

Linear regression analysis was performed between the pulmonary function test results and the right ventricular dimension index (RVD index) which is the RVD divided by the body surface area and expressed in cm/m Septal motion was classified as normal (N) reversed (abnormal type A) or flattened (abnormal type B) (1) Abnormal septal motion occurred when the right ventricular cavity was dilated (2) Each patient underwent only one echocardiographic examination

Forced vital capacity (FVC) was measured using a McKesson Vitalor and peak-expiratory flow rate (PEFR) with a Wright anemometer Results were expressed as per cent of the predicted value based on the patient s height and sex The normal values for FVC given by Lyons et al (9) were used and for PEFR the normal values from this department were used (5)

Septal motion was classified as normal (N=3) abnormal type A (N=6) abnormal type B (N=1) and abnormal type A–B with pronounced respiratory fluctuations (N=1) in those 11 patient with RVD index above 2 2 Septal motion was classified as normal (N=13) abnormal type A (N=2) and abnormal type B (N=5) in those 20 patients with RVD index lower than 2 2 Abnormal septal motion was chiefly observed in patients with raised RVD index

Heart failure and electrocardiographic findings

Five patients had other signs of heart involvement in addition to raised RVD index These patients are lettered in the figures

Patient A Nineteen year old woman with periferal edema and enlargement of the liver but no extended neck veins ECG showed a right axis deviation RVD index was 2 5 and septal motion abnormal type A

Patient B Five years old girl with liver congestion and extended neck veins but no periferal edema ECG showed a right axis deviation P in lead II 2 5 mm and S in V_6 over 5 mm RVD index was 4 7 and septal motion abnormal type A She died 8 weeks later No autopsy

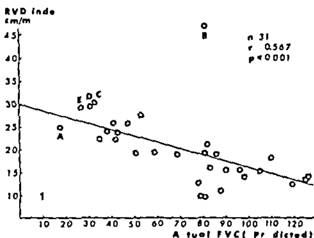
Patient C Seven year old boy without heart failure ECG showed a right axis deviation RVD index was 3 0 and septal motion abnormal type A–B with excessive respiratory fluctuations

Patient D Eight year old girl with slight distension of neck veins but no periferal edema or liver congestion ECG showed a right axis deviation and P in lead II 2 5–3 mm RVD index was 2 9 and septal motion was normal

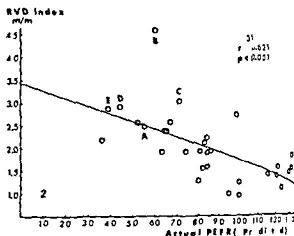
Patient E Nine year old boy with enlargement of the liver and distended neck veins but no edema or electrocardiographic changes RVD index was 2 9 and septal motion abnormal type A

DISCUSSION

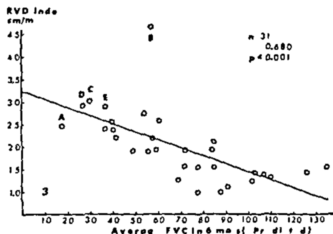
The echocardiographic investigation has demonstrated that patients with severe pulmonary changes have an abnormally increased RVD Furthermore there was a significant relationship between increasing RVD index and decreasing pulmonary function test results Because RVD is measured between the right ventricular epicardium and the right septal surface an increased RVD reflects right ventricular dilatation and/or hypertrophy Probably this suggests that these patients have cor pulmonale which is a wellknown complication to CF (3 11 15)



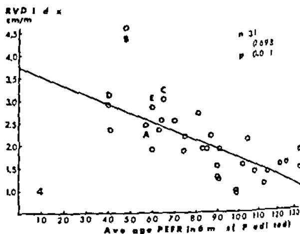
As an increase of RVD can also be obtained by a rotation of the heart bringing a larger part of the right ventricle within the ultrasonic beam serial measurements on the individual patient could of course be of greater value in predicting the existence of cor pulmonale



Because pulmonary artery pressure is not measured and angiocardiography is not carried out in our patients we have no further informations about right ventricular anterior wall or cavity Therefore an evaluation of the echocardiographic findings from a hemodynamic point of view is not possible



Rosenthal et al (14) found a significant correlation between *actual* pulmonary function test results and RVD index This finding is confirmed by our investigation with a still higher correlation coefficient Furthermore a highly significant correlation is found between average six months values for pulmonary function test and RVD index suggesting a persistent heart involvement



Generally the relationship between RVD and right ventricular volume and pressure is insufficiently explained

Lundstrom et al (8) found a fairly good relationship between increased RVD and right ventricular size based on the angiogram Increased RVD is found chiefly in patients with right ventricular volume overload (1 2 6 7 10 13 16 17) but also in some patients with pressure overload (1 4 6 7)

Figs. 1–4. Increasing right ventricular dimension index correlates significantly with decreasing actual forced vital capacity (Fig. 1), actual peak expiratory flow rate (Fig. 2), average forced vital capacity in 6 months (Fig. 3) and average peak expiratory flow rate in 6 months (Fig. 4). A–E represent patients with other heart symptoms. See text. RVD index=right ventricular dimension index. FVC=forced vital capacity. PEFR=peak expiratory flow rate.

RESULTS

Echocardiographic findings

Thirty one patients with body surface areas above 0.65 m² had RVD values between 1.4 and 4.3 cm (average 2.3 cm). Thirty controls with body surface areas above 0.65 m² too had RVD values between 1.3 and 2.2 cm (average 1.6 cm). RVD of 14 patients were found higher than the upper normal limit.

In the control group RVD index varied between 1.0 and 2.2 cm/m² and in the patient group between 1.0 and 4.7 cm/m². Eleven patients had RVD index above the upper normal limit.

Increasing RVD index correlated significantly with decreasing actual FVC ($r=-0.567$, $p<0.001$) and actual PEFR ($r=-0.621$, $p<0.001$) (Figs. 1 and 2).

Furthermore, RVD index was related to average values in 6 months for FVC and PEFR with the purpose to determine whether the finding of raised RVD index was caused by an acute or by a persistent decrease in pulmonary function. As our patients are frequently seen in the outpatient clinic 6 to 19 pulmonary function test results over a 6 month period in each patient are available. Figs. 3 and 4 show a highly significant correlation between increasing RVD index and decreasing average 6 month values for FVC ($r=-0.680$, $p<0.001$) and for PEFR ($r=-0.698$, $p<0.001$). This suggest a persistent heart involvement as a result of chronic pulmonary alterations.

Septal motion was classified as normal (N= 3) abnormal type A (N=6) abnormal type B (N=1) and abnormal type A–B with pronounced respiratory fluctuations (N=1) in those 11 patient with RVD index above 2 2 Septal motion was classified as normal (N= 13) abnormal type A (N=2) and abnormal type B (N=5) in those 20 patients with RVD index lower than 2 2 Abnormal septal motion was chiefly observed in patients with raised RVD index

Heart failure and electrocardiographic findings

Five patients had other signs of heart involvement in addition to raised RVD index These patients are lettered in the figures

Patient A Nineteen year old woman with periferal edema and enlargement of the liver but no extended neck veins ECG showed a right axis deviation RVD index was 2 5 and septal motion abnormal type A

Patient B Five years old girl with liver congestion and extended neck veins but no periferal edema ECG showed a right axis deviation P in lead II 2 5 mm and S in V_6 over 5 mm RVD index was 4 7 and septal motion abnormal type A She died 8 weeks later No autopsy

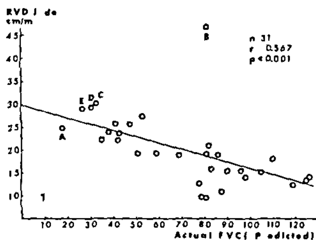
Patient C Seven year old boy without heart failure ECG showed a right axis deviation RVD index was 3 0 and septal motion abnormal type A–B with excessive respiratory fluctuations

Patient D Eight year old girl with slight distension of neck veins but no periferal edema or liver congestion ECG showed a right axis deviation and P in lead II 2 5–3 mm RVD index was 2 9 and septal motion was normal

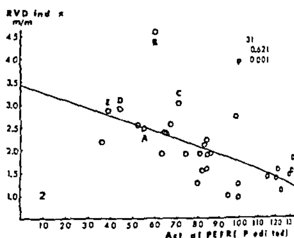
Patient E Nine year old boy with enlargement of the liver and distended neck veins but no edema or electrocardiographic changes RVD index was 2 9 and septal motion abnormal type A

DISCUSSION

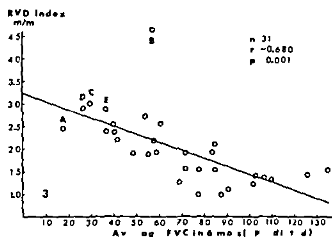
The echocardiographic investigation has demonstrated that patients with severe pulmonary changes have an abnormally increased RVD Furthermore there was a significant relationship between increasing RVD index and decreasing pulmonary function test results Because RVD is measured between the right ventricular epicardium and the right septal surface an increased RVD reflects right ventricular dilatation and/or hypertrophy Probably this suggests that these patients have cor pulmonale which is a wellknown complication to CF (3 11 15)



As an increase of RVD can also be obtained by a rotation of the heart bringing a larger part of the right ventricle within the ultrasonic beam serial measurements on the individual patient could of course be of greater value in predicting the existence of cor pulmonale



Because pulmonary artery pressure is not measured and angiocardiography is not carried out in our patients we have no further informations about right ventricular anterior wall or cavity Therefore an evaluation of the echocardiographic findings from a hemodynamic point of view is not possible



Rosenthal et al (14) found a significant correlation between *actual* pulmonary function test results and RVD index This finding is confirmed by our investigation with a still higher correlation coefficient Furthermore a highly significant correlation is found between average six months values for pulmonary function test and RVD index suggesting a persistent heart involvement

Patient E Nine year old boy with enlargement of the liver and distended neck veins but no edema or electrocardiographic changes RVD index was 2 9 and septal motion abnormal type A

DISCUSSION

The echocardiographic investigation has demonstrated that patients with severe pulmonary changes have an abnormally increased RVD Furthermore there was a significant relationship between increasing RVD index and decreasing pulmonary function test results Because RVD is measured between the right ventricular epicardium and the right septal surface an increased RVD reflects right ventricular dilatation and/or hypertrophy Probably this suggests that these patients have cor pulmonale which is a wellknown complication to CF (3 11 15)

As an increase of RVD can also be obtained by a rotation of the heart bringing a larger part of the right ventricle within the ultrasonic beam serial measurements on the individual patient could of course be of greater value in predicting the existence of cor pulmonale

Because pulmonary artery pressure is not measured and angiocardiography is not carried out in our patients we have no further informations about right ventricular anterior wall or cavity Therefore an evaluation of the echocardiographic findings from a hemodynamic point of view is not possible

Rosenthal et al (14) found a significant correlation between *actual* pulmonary function test results and RVD index This finding is confirmed by our investigation with a still higher correlation coefficient Furthermore a highly significant correlation is found between average six months values for pulmonary function test and RVD index suggesting a persistent heart involvement

Generally the relationship between RVD and right ventricular volume and pressure is insufficiently explained

Lundstrom et al (8) found a fairly good relationship between increased RVD and right ventricular size based on the angiogram Increased RVD is found chiefly in patients with right ventricular volume overload (1 2 6 7 10 13 16 17) but also in some patients with pressure overload (1 4 6 7)

Further analysis of the relationship between clinical condition and RVD index is not performed because we don t employ clinical scoring However the five lettered patients with other signs of heart involvement have increased RVD index and the highest RVD index was determined in patient B who died 8 weeks after the examination

It is a wellknown observation that electrocardiographic evidence of right ventricular involvement is not a consistent finding in patients with cor pulmonale (12) So it is not surprising that electrocardiographic abnormalities are found in only four patients

The present study has shown the usefulness of echocardiographic measurement of right ventricular dimension and septal motion in assessing cor pulmonale before development of electrocardiographic abnormalities and right heart failure

ABSTRACT Thong Y H and Rencis V (Department of Paediatrics University of Adelaide Adelaide Children s Hospital North Adelaide 5006 South Australia Australia) Bilirubin inhibits hexose monophosphate shunt activity of phagocytosing neutrophils Acta Paediatr Scand 66 757 1977 —Neutrophil hexose monophosphate (H M P) shunt activity was measured by the conversion of 14C 1 glucose to $^{1}CO_2$ during ingestion of polystyrene latex particles Unconjugated bilirubin at the concentration of 1×10^{5} M was found to markedly inhibit H M P shunt activity Since H M P shunt activity of neutrophils is an important prerequisite of microbicidal function it is suggested that jaundiced newborns may be more susceptible to bacterial infections

KEY WORDS Bilirubin neutrophils hexose monophosphate shunt

Although the extraneural toxicity of unconjugated bilirubin has been known for many years (13 4) the adverse effects on the immune system have only recently been recognised Ansaldi et al (1) reported lower immunoglobulin levels in infants with neonatal jaundice Others have found impaired antibody production following immunization with diphtheria pertusis tetanus (11) and measles (7) Inhibition of lymphocyte responsiveness to phytohaemagglutinin stimulation has also been noted (6 15) We have studied the effect of unconjugated bilirubin on neutrophil function as measured by glucose oxidation via the hexose monophosphate (H M P) shunt during phagocytosis of latex particles (3)

MATERIALS AND METHODS

Polymorphonuclear leukocytes from healthy donors were purified by centrifugation 30 min at 00 G on a hypaque ficoll gradient S G 1095 Cells were washed twice and resuspended in glucose free Earl s solution Viability was assessed by trypan blue dye exclusion at the beginning and end of experiments Experiments were performed in Warburg flasks in 1 ml volumes (3) Stimulated flasks contained ?–4×10^{6} cells ml^{-1} 1 5×10 ^{8} M C 1 glucose and 0 1 ml of 1 3 dilution of 0 80 μ size polystyren latex particles Latex particles were omitted from unstimulated flasks Test flasks contained appropriate concentrations of unconjugated bilirubin solubilized in 10^{-4} M sodium carbonate Control flasks contained similar concentrations of the solvent only Flasks were incubated for 45 min on a shaking water bath at 37°C the $^{1}CO_2$ captured by 0 1 ml of 5 N NaOH in the centre well and counted in a Packard tricarb scintillation counter Inhibition of H M P shunt activity was calculated as follows

% inhibition=

$$100 - \frac{\text{cpm stimulated containing bilirubin} - \text{cpm unstimulated}}{\text{cpm stimulated without bilirubin} - \text{cpm unstimulated}} \times 100$$

In order to determine whether phagocytosis of latex particles was affected by bilirubin a separate set of experiments were performed as described above except that at the end of the incubation period the cells were placed on glass slides and the number of particles per 100 cells determined by microscopic observation

Further analysis of the relationship between clinical condition and RVD index is not performed because we don t employ clinical scoring However, the five lettered patients with other signs of heart involvement have increased RVD index and the highest RVD index was determined in patient B who died 8 weeks after the examination

It is a wellknown observation that electrocardiographic evidence of right ventricular involvement is not a consistent finding in patients with cor pulmonale (12) So it is not surprising that electrocardiographic abnormalities are found in only four patients

The present study has shown the usefulness of echocardiographic measurement of right ventricular dimension and septal motion in assessing cor pulmonale before development of electrocardiographic abnormalities and right heart failure

BILIRUBIN INHIBITS HEXOSE MONOPHOSPHATE SHUNT ACTIVITY OF PHAGOCYTOSING NEUTROPHILS

Y H THONG and V RENCIS

From the Department of Paediatrics University of Adelaide Adelaide Children s Hospital North Adelaide South Australia Australia

ABSTRACT Thong Y H and Rencis V (Department of Paediatrics University of Adelaide Adelaide Children s Hospital North Adelaide 5006 South Australia Australia) Bilirubin inhibits hexose monophosphate shunt activity of phagocytosing neutrophils Acta Paediatr Scand 66 757 1977.—Neutrophil hexose monophosphate (H M P) shunt activity was measured by the conversion of 14C 1-glucose to $^{14}CO_2$ during ingestion of polystyrene latex particles Unconjugated bilirubin at the concentration of 1×10^{5} M was found to markedly inhibit H M P shunt activity Since H M P shunt activity of neutrophils is an important prerequisite of microbicidal function it is suggested that jaundiced newborns may be more susceptible to bacterial infections

KEY WORDS Bilirubin neutrophils hexose monophosphate shunt

Although the extraneural toxicity of unconjugated bilirubin has been known for many years (13 4) the adverse effects on the immune system have only recently been recognised Ansaldi et al (1) reported lower immunoglobulin levels in infants with neonatal jaundice Others have found impaired antibody production following immunization with diphtheria pertusis tetanus (11) and measles (7) Inhibition of lymphocyte responsiveness to phytohaemagglutinin stimulation has also been noted (6 15) We have studied the effect of unconjugated bilirubin on neutrophil function as measured by glucose oxidation via the hexose monophosphate (H M P) shunt during phagocytosis of latex particles (3)

MATERIALS AND METHODS

Polymorphonuclear leukocytes from healthy donors were purified by centrifugation 30 min at 700 G on a hypaque ficoll gradient S G 1 095 Cells were washed twice and resuspended in glucose free Earl's solution Viability was assessed by trypan blue dye exclusion at the beginning and end of experiments Experiments were performed in Warburg flasks in 1 ml volumes (3) Stimulated flasks contained $2–4\times10^{6}$ cells ml 1 5×10^{-8} M ^{14}C 1 glucose and 0 1 ml of 1 3 dilution of 0 80 μ size polystyrene latex particles Latex particles were omitted from unstimulated flasks Test flasks contained appropriate concentrations of unconjugated bilirubin solubilized in 10 M sodium carbonate Control flasks contained similar concentrations of the solvent only Flasks were incubated for 45 min on a shaking water bath at 37°C the CO captured by 0 1 ml of 5 N NaOH in the centre well and counted in a Packard tricarb scintillation counter Inhibition of H M P shunt activity was calculated as follows

% inhibition=

$$100 - \frac{\text{cpm stimulated containing bilirubin} - \text{cpm unstimulated}}{\text{cpm stimulated without bilirubin} - \text{cpm unstimulated}} \times 100$$

In order to determine whether phagocytosis of latex particles was affected by bilirubin a separate set of experiments were performed as described above except that at the end of the incubation period the cells were placed on glass slides and the number of particles per 100 cells determined by microscopic observation

Further analysis of the relationship between clinical condition and RVD index is not performed because we don t employ clinical scoring However the five lettered patients with other signs of heart involvement have increased RVD index and the highest RVD index was determined in patient B who died 8 weeks after the examination

It is a wellknown observation that electrocardiographic evidence of right ventricular involvement is not a consistent finding in patients with cor pulmonale (12) So it is not surprising that electrocardiographic abnormalities are found in only four patients

The present study has shown the usefulness of echocardiographic measurement of right ventricular dimension and septal motion in assessing cor pulmonale before development of electrocardiographic abnormalities and right heart failure

Table 1 *Effect of bilirubin on H M P shunt activity of phagocytosing neutrophils*

Bilirubin concentration	% Inhibition (Mean ± S E of 5 experiments)	Statistical difference compared to control (t test)
0 (control)	0	–
1×10^{-5} M	51±7	$p<0.01$
5×10^{-6} M	23±8	$p>0.05$
1×10^{-6} M	10±3	$p>0.05$

Table 2 *Effect of albumin on bilirubin induced suppression of H M P shunt activity*

Bilirubin concentration	Albumin concentration	% Inhibition (Mean ± S E of 5 experiments)
0 (control)	0	0
10^{-5} M	0	63±5[a]
10^{-5} M	10^{-5} M	11±6[b]
10^{-5} M	10^{-6} M	27±11[b]

[a] Inhibition by 10^{-5} M bilirubin of 63±5% is not significantly different from 51±7% obtained in the first set of experiments (Unpaired t test $p>0.2$)
[b] Significant reversal of bilirubin induced suppression of H M P shunt activity by 10^{-5} M albumin ($p<0.01$) but not by 10^{-6} M albumin ($p>0.05$)

RESULTS

Phagocytosis of latex particles did not appear to be affected by the presence of unconjugated bilirubin The number of particles phagocytosed per 100 cells were 124 8±12 4 (mean± S E of 6 experiments) in the presence of 1×10^{-5} M bilirubin compared to 115 3×10 9 in controls ($p>0.6$)

Basal H M P shunt activity was also unaffected by the concentrations of bilirubin used in these experiments In contrast there was marked inhibition of H M P shunt activity of 51±7% on stimulated neutrophils at bilirubin concentration of 10^{-5} M (Table 1) In a separate set of experiments it was also found that equimolar concentrations of albumin reversed the inhibitory effect of bilirubin (Table 2)

DISCUSSION

During phagocytosis there is a marked increase in glucose oxidation via the hexose monophosphate shunt resulting in the production of hydrogen peroxide and superoxide important chemical mediators of microbial killing (9) Unconjugated bilirubin is known to affect a number of cellular enzyme systems (5 10 12 18) but the mechanism by which bilirubin inhibits neutrophil H M P shunt activity is unclear One explanation may be its known effect on the enzyme N A D H oxidase (5) This enzyme located primarily on the plasma membrane of neutrophils is deficient in chronic granulomatous disease (2 16) In the normal sequence of events the plasma membrane is invaginated to form the phagosome N A D H oxidase is activated hydrogen peroxide diffuses through the cytoplasm which in turn stimulates H M P shunt activity (9)

The clinical significance of our findings is difficult to evaluate The concentration of bilirubin (10^{-5} M) which affects neutrophil function in vitro corresponds to a serum level of 0 6 mg per 100 ml and is within the physiologic range Its tight binding to albumin (14) would prevent a deleterious effect on cells However in clinical states of hyperbilirubinaemia, albumin binding capacity can be saturated and neutrophil function impaired This may in part account for the observation that patients with congenital atresia of the bile ducts where a substantial fraction of serum bilirubin may be of the unconjugated variety have an increased susceptibility to intercurrent infection (17) Moreover jaundice is the second most common clinical feature associated with neonatal sepsis (8) Although neonatal hyperbilirubinaemia is generally regarded as a consequence of sepsis rather than a predisposing cause clinical studies to clarify this issue may prove rewarding

ACKNOWLEDGEMENTS

Supported in part by the Adelaide Children s Hospital Research Trust We wish to thank Professor George Maxwell for stimulating discussion and Geoffrey Harvey and Dietmar Ness for assistance

THE OCCURRENCE AND ORIGIN OF DDT IN HUMAN MILK

ERKKI VUORI HILKKA TYLLINEN PEKKA KUITUNEN and AILA PAGANUS

From the Milk Bank of the Children s Hospital the Department of Public Health Science University of Helsinki and the State Veterinary Medical Institute Helsinki Finland

ABSTRACT Vuori E Tyllinen H Kuitunen P and Paganus A (The Milk Bank of the Children s Hospital the Department of Public Health Science University of Helsinki and the State Veterinary Medical Institute Helsinki Finland) The occurrence and origin of DDT in human milk Acta Paediatr Scand 66 761 1977.—Gas chromatography has been applied for the analysis of organochlorine compounds of 49 samples of human milk The average total DDT (2,2 bis(4-chlorophenyl)1 1 1 trichloroethane) content in human milk was found to be 0 058 mg/kg ranging from 0 017–0 17 mg/kg (1 57 mg/kg milk fat with a range of 0 50–4 00 mg/kg) Thirty four cases contained traces of dieldrin but the content of dieldrin reached 0 008 mg/kg in only one milk sample The average content of PCB (polychlorinated biphenyls) was 0 024 mg/kg of human milk with a range of 0 011–0 054 mg/kg (0 65 mg/kg of milk fat with a range of 0 33–1 10 mg/kg) The ratio of DDT meta bolites/DDT varied from 1 1 to 7 8 (mean 2 8) Studies were also made of the effect of the weight weight loss diet smoking habits and parity of the nursing mother upon the content of organochlorine compounds in human milk A significant positive correlation was observed between the DDT content of human milk fat and cigarette smoking

The average daily intake of total DDT for Finnish breastfed babies was calculated to be 0 0093 mg/kg 1 9 times more than the daily intake of 0 005 mg/kg indicated by FAO/WHO as the acceptable value

KEY WORDS Insecticides polychlorobiphenyl compounds human milk

The discovery of DDT in human milk (7) has been followed by a number of reports upon the harmful action of DDT in the biosphere (13) Published information of this type has led to a ban being imposed on the use of DDT as a pesticide in many countries In Finland the use of DDT has been restricted since 1971 and completely forbidden with effect from January 1 1977 Some researchers have looked for factors which influence the DDT content of human milk Studies have included food stuffs (3 15) the domestic use of pesticides (3 8 15) the parity (3 6) and weight of the nursing mother (5) and recently cigarette smoking (3) What determines the DDT levels in human milk in a country where the use of DDT has been restricted for years? With a view to the solution of this problem analyses have been made of the content of organochlorine compounds (OCC) of 49 human milk samples along with an investigation of the possible sources of DDT in human beings

MATERIALS AND METHODS

Random collections were made of 49 individual human milk samples during the period November 1973 to March 1974 from donors of the Milk Bank of the Children s Hospital University of Helsinki All of the donors were living in the Helsinki metropolitan area To each one there

MATERIALS AND METHODS

Random collections were made of 49 individual human milk samples during the period November 1973 to March 1974 from donors of the Milk Bank of the Children s Hospital University of Helsinki All of the donors were living in the Helsinki metropolitan area To each one there

Table 1 *Age weight weight loss (post partum) phase of lactation of the donor group fat concentration and the average amount of milk donated daily*

Fat concentration 49 observations otherwise 46

	Mean	S D	Range
Age (years)	26 3	3 4	20–35
Weight (kg)	65 0	11 9	46–112
Weight loss (kg/month)	2 0	1 5	0 0–7 5
Phase of lactation (days)	41 4	33 7	10–152
Fat concentration (%)	3 7	0 9	2 2–7 1
Milk donated (ml/day)	351	321	45–1 975

was sent a questionnaire concerned with the weight weight loss diet (particularly the consumption of fat fish meat meat products and liver) smoking habits and parity of the mothers The per cent completing the questionnaire was 93 9 (46/49) The average amount of milk donated daily was registered

The samples of human milk were weighed and dried with anhydrous sodium sulphate The fat was extracted and the OCC were purified by thin layer chromatography The analyses were carried out by gas chromatography To ensure the accuracy of identification the analyses were performed twice with two different types of columns The degree of purity of the standards for the determinations of DDT DDE DDD and dieldrin was 99% (Analytical Standards Ltd Sweden) The standards for the determination of PCB were prepared from a technical grade product (Clophen A 60) with a chlorine content of 60% A detailed account of the method has been published earlier (12) The analyses were carried out in the State Veterinary Medical Institute

RESULTS

The mean age of the donors was 26 3 years the mean phase of lactation was 41 4 days post partum and the mean fat concentration

Table 2 *Dietary habits of the donors*

The numbers indicate percentages of mothers in each dietary habits group

	More than 3 times a week	Only 1–2 times a week	Only 1–2 times a month	No

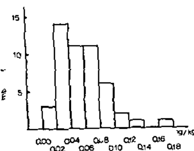

Fig 1 Distribution of different levels of total DDT in human milk

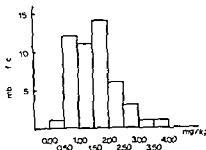

Fig 2 Distribution of different levels of total DDT in human milk fat

human milk and Fig 2 the corresponding distribution for human milk fat

A significant correlation was observed between cigarette smoking and the concentration of DDT and an almost significant correlation between cigarette smoking and the total DDT concentration as is evident from Table 4 No significant correlation was apparent between the dietary habits investigated and the concentrations of DDT total DDT and PCB Moreover no significant correlations were observable between the concentrations of OCC and the age the phase of lactation amount of donated milk parity weight and weight loss of the donors

DISCUSSION

In comparison with other European countries the level of OCC of human milk is low in Finland (Table 5) It can be seen that the total DDT concentration in human milk has diminished in Sweden during recent years whereas the concentration of PCB has increased A diminution in DDT levels following the restriction of its use has also been evident elsewhere (5) The low levels of DDT in Finland are understandable as the use of DDT has never been extensive in this country during the period 1946–1971 sales of DDT here amounted to a total of 304 tons (9)

Kroger (6) has found that the concentrations of DDT in the milk fat of mothers who had nursed three or more babies were below average The results obtained by Wilson et al (15) demonstrated a fall in DDT levels with increasing maternal age although the findings of Knoll & Jayaraman (5) were directly opposed to this Recently Bradt & Herrenkohl (3) have found that the number of children nursed accounted statistically for 21 % of the variance in total DDT They also calculated that during nursing an average American mother excretes twice the mean daily intake of DDT In the present study no significant correlation was apparent between maternal age or parity and the OCC levels of human milk This may be explained by the fact that the majority of the mothers were nursing their first infant and only one mother her third Wilson et al (15) have also studied the dietary habits of mothers and they found no significant correlations between the total DDT concentrations in

The authors give a value of 3 24 mg/kg of milk *fat* The value in the table has been calculated on the assumption that the fat concentration of human milk averages 4%
[b] Present study

milk and the habit of eating fish or meat Our results are in agreement with this observation

Knoll & Jayaraman (5) found that the milk of obese women contained lower amounts of OCC than did that of women of normal weight In the present study no correlation was observable between the OCC content of milk and the weight or post partum weight loss of the donor

Bradt & Herrenkohl (3) have shown that the mean total DDT for non smokers was lower than for cigarette smokers 15% of the variance of total DDT was explicable by the number of cigarettes smoked daily In this study it became evident that cigarette smoking showed a significant correlation with the DDT concentrations in milk fat These correlations are understood when one considers that tobacco plants are regularly treated with DDT (10) It is obvious that in Finland where DDT has not been used for years a large proportion of DDT comes from cigarettes this is further supported by the finding that cigarette smoking has a closer correlation with the DDT than with the total DDT (including the metabolites of DDT) content of milk fat (Table 4)

According to the calculations of Westoo & Noren (14) a Finnish infant weighing 5 kg who consumes 800 g of milk a day would receive an average daily dose of 0 0093 mg/kg of total DDT Although this is among the lowest values in the world it is nevertheless almost twice as much as ADI value of 0 005 mg/kg indicated by FAO/WHO (16)

Although at present the OCC residues in human milk do not offer any threat to public health in Finland we must agree with the statement by Wasserman et al (13) that The greatest exposure of the general population nonoccupationally exposed to OCC is that of infants fed by mother s milk This fact in conjunction with the marked positive correlation between cigarette smoking and the DDT content of human milk provides further reason to advise women not to smoke

REVIEW ARTICLE

DRUG USAGE AND ADVERSE DRUG REACTIONS IN PAEDIATRIC PATIENTS

J WHYTE and E GREENAN

From the University Department of Child Health and the Royal Hospital for Sick Children Yorkhill Glasgow Scotland

ABSTRACT Whyte J and Greenan E (University Department of Child Health Royal Hospital for Sick Children Glasgow Scotland) Drug usage and adverse drug reactions in paediatric patients Acta Paediatr Scand 66 767 1977 —The development of epidemiological methods for the study of adverse drug reactions is reviewed in connection with the presentation of data obtained by intensive monitoring of 1 000 admissions to a medical paediatric unit Compared with adults and American children the patients received fewer drugs and experienced fewer reactions while in hospital The drug usage pattern was different from that of American paediatric practice and general practice in the United Kingdom Fifty-one (6%) patients experienced 119 adverse drug reactions These occurred more frequently in children suffering from serious disorders and in the majority of cases the basic therapy was continued regardless of the severity of the drug side effects Treatment was required for the effects of 66 (55%) adverse reactions It appears that drug monitoring in paediatric practice may be of greater value if surveillance programmes are designed to provide a therapeutic audit and extended to include children receiving drugs in the community

KEY WORDS Drug usage drug surveillance adverse drug reactions drug monitor

Concern about the hazards of drug therapy has grown with the increasing availability of potent medicines and has led to the introduction of methods designed to investigate the prevalence nature and significance of adverse drug reactions (21)

Following the thalidomide disaster of the early 1960 s spontaneous reporting of adverse reactions was encouraged by the development of central registries which collated the reports and instituted further enquiries The increased volume of information obtained in this way has enabled these agencies to publish comprehensive lists of the side-effects of many drugs but the continuing failure of practitioners to report many of the adverse reactions which they encounter has prevented the registries from assessing the frequency with which drug induced disorders occur in the community (22)

The potential value of intensive drug monitoring in hospitals was demonstrated by pilot studies in several centres (6 18 19 25) and much valuable information has been obtained from event orientated and drug orientated surveys conducted in the hospital setting (3 16) Coull and his co workers have demonstrated the particular value of the latter approach used in conjunction with a regional drug information system and have described the detailed investigation of suspected drug reactions (3 4) It is apparent however that this method has been of greatest value when used to test pre existing hypotheses about drug effect associations and that it cannot by the nature of its design act as an alerting system Similarly it is unable to measure the prevalence of iatrogenic disease in a hospital population exposed to many drugs

5 Irritant—causing irritation of epithelial surfaces
6 Mechanism unknown

Analysis of factors predisposing to the development of adverse reactions

Statistical analysis was carried out to test the significance of factors predisposing to adverse drug reactions As in other studies only reactions which were definite or probable were included When testing the relationships between drug reactions and the number of drugs administered only admission episodes complicated by reactions to hospital therapy were included as data on pre admission drug usage were unreliable for reasons already reported (23)

The number of patients experiencing adverse reactions was too small to permit standardisation for all of the variants

RESULTS

Population and drug usage

During the survey period 932 admission episodes involving 844 children (499 males) were studied The average duration of stay in the unit was 8 9 days younger children predominated (Table 1) and respiratory infection was the most frequently recorded diagnosis (Table 2) Accidental ingestion of foreign substances caused the admission of 52 patients 35 of whom were poisoned by drugs not in current use by the affected children

Over the ten month period of the study 2 179 *prescriptions were recorded* an average of 2 3 drugs per patient admission or 0 26 per patient per day (usage corrected for duration of stay) Two hundred and forty nine (26 7%) patients did not receive drugs after admission and this occurred most frequently in children

Table 2 *Most frequently recorded primary discharge diagnoses*

Patient orientated comprehensive drug surveillance has not been limited in these ways and has been used successfully in many centres throughout the world (11) In studies which have used this method the clinical progress of a cohort of patients admitted to a surveyed area (e g a medical ward) has been monitored by doctors pharmacists or nurses (5 7 8 19) to obtain details of drug usage (denominator data) and adverse drug reactions (numerator data) The data obtained have allowed more accurate measurement of the incidence of adverse drug effects and have enabled workers to delineate groups of patients at particular risk e g the elderly (7) Also when applied on a large scale co operative basis the method has successfully detected previously unsuspected drug interactions and reports have suggested that it may be of use for the assessment of drug efficacy (9 20)

Similar work in paediatrics has been on a smaller scale but has highlighted the differences which exist between the drug usage and adverse drug reactions of children and adults (2 13) However by adopting a purely epidemiological approach these studies have failed to relate the clinical effects of drug induced disorders to the severity and prognoses of the diseases under treatment and have not allowed the clinician to assess their significance in relation to his own therapeutic practice

This paper describes our experience with a comprehensive drug surveillance programme carried out to obtain data for comparison with other published results and to assess the clinical importance of adverse drug effects in the therapeutic setting in which they occurred

METHOD

Successive admissions to a medical paediatric unit (48 beds) with regional responsibilities for cardiac investigation and the treatment of leukaemia were intensively monitored using a method similar to that of Slone and his co-workers (19) One thousand admission episodes involving 909 children occurred over a 10 month period but 68 were excluded from the study when the children required general anaesthetic or were transferred to an other ward

A research nurse (E G) acting as the drug monitor interviewed parents to obtain details of pre admission therapy and previous adverse drug reactions A record of each child s age sex weight height diagnosis and duration of stay in hospital was also completed By visiting the wards daily examining medical and nursing records and attending clinical ward rounds the monitor detected adverse events which might have been due to drug therapy When a suspected adverse drug reaction was reported the study team together with the physician in charge of the patient reviewed the circumstances to decide if a relationship existed between the adverse event and the drugs administered Adverse reactions detected in this way were then studied further to determine their nature severity and mechanisms and their effects on the clinical management of the patient Data obtained were recorded on standard forms and entered on a computer file for analysis

Definitions and classifications

An adverse reaction was defined as any undesired or unintended response to the patient s own current medication, thus excluding accidental poisoning by other drugs or substances

Probability of adverse drug reactions

Reactions were classified as

Definite directly attributable to a drug having a clear temporal relationship to the time of administration and confirmed by positive rechallenge or laboratory investigation e g evidence of abnormal blood levels etc

Probable occurring with a clear temporal relationship to administration and improving on withdrawal of therapy

Possible having some temporal relationship to administration but the effects could have been due to the basic illness

Severity of adverse reactions

Reaction severity was classified as

1 Causing death
2 Life threatening—demanding immediate action to prevent death
3 Severe—necessitating the use of supportive therapy prolonging the patient s admission by 3 or more days or causing admission to hospital and resulting in either of the above
4 Moderate—necessitating the administration of an antidote or symptomatic treatment prolonging admission by 1–3 days or causing admission and resulting in either of the above
5 Mild—incidental in the patient s progress and not requiring treatment

Mechanisms of adverse reactions

To provide a classification of the mechanisms of adverse drug reactions which could be readily interpreted in the clinical situation a modification of schemes suggested by several authors was adopted (5 7 17 18)

Reactions were classified as

1 Intended effect excessive *(TOXIC)* (*a*) with overdosage (according to Clark s rule) (*b*) without overdosage (*c*) potentiation—possible additive effect of drugs with similar actions

5 Irritant—causing irritation of epithelial surfaces
6 Mechanism unknown

Analysis of factors predisposing to the development of adverse reactions

Statistical analysis was carried out to test the significance of factors predisposing to adverse drug reactions As in other studies only reactions which were definite or probable were included When testing the relationships between drug reactions and the number of drugs administered only admission episodes complicated by reactions to hospital therapy were included as data on pre admission drug usage were unreliable for reasons already reported (23)

The number of patients experiencing adverse reactions was too small to permit standardisation for all of the variants

RESULTS

Population and drug usage

During the survey period 932 admission episodes involving 844 children (499 males) were studied The average duration of stay in the unit was 8 9 days younger children predominated (Table 1) and respiratory infection was the most frequently recorded diagnosis (Table 2) Accidental ingestion of foreign substances caused the admission of 52 patients 35 of whom were poisoned by drugs not in current use by the affected children

Over the ten month period of the study 2 179 prescriptions were recorded an average of 2 3 drugs per patient admission or 0 26 per patient per day (usage corrected for duration of stay) Two hundred and forty nine (26 7%) patients did not receive drugs after admission and this occurred most frequently in children

Patient orientated comprehensive drug surveillance has not been limited in these ways and has been used successfully in many centres throughout the world (11) In studies which have used this method the clinical progress of a cohort of patients admitted to a surveyed area (e g , a medical ward) has been monitored by doctors pharmacists or nurses (5 7, 8 19) to obtain details of drug usage (denominator data) and adverse drug reactions (numerator data) The data obtained have allowed more accurate measurement of the incidence of adverse drug effects and have enabled workers to delineate groups of patients at particular risk e g the elderly (7) Also when applied on a large scale co operative basis the method has successfully detected previously unsuspected drug interactions and reports have suggested that it may be of use for the assessment of drug efficacy (9 20)

Similar work in paediatrics has been on a smaller scale but has highlighted the differences which exist between the drug usage and adverse drug reactions of children and adults (2 13) However, by adopting a purely epidemiological approach, these studies have failed to relate the clinical effects of drug induced disorders to the severity and prognoses of the diseases under treatment and have not allowed the clinician to assess their significance in relation to his own therapeutic practice

This paper describes our experience with a comprehensive drug surveillance programme carried out to obtain data for comparison with other published results and to assess the clinical importance of adverse drug effects in the therapeutic setting in which they occurred

METHOD

Successive admissions to a medical paediatric unit (48 beds) with regional responsibilities for cardiac investigation and the treatment of leukaemia were intensively monitored using a method similar to that of Slone and his co-workers (19) One thousand admission episodes involving 909 children occurred over a 10 month period but 68 were excluded from the study when the children required general anaesthetic or were transferred to an other ward

A research nurse (E G) acting as the drug monitor interviewed parents to obtain details of pre admission therapy and previous adverse drug reactions A record of each child s age sex weight height diagnosis and duration of stay in hospital was also completed By visiting the wards daily examining medical and nursing records and attending clinical ward rounds the monitor detected adverse events which might have been due to drug therapy When a suspected adverse drug reaction was reported the study team together with the physician in charge of the patient reviewed the circumstances to decide if a relationship existed between the adverse event and the drugs administered Adverse reactions detected in this way were then studied further to determine their nature severity and mechanisms and their effects on the clinical management of the patient Data obtained were recorded on standard forms and entered on a computer file for analysis

Definitions and classifications

An adverse reaction was defined as any undesired or unintended response to the patient s own current medication thus excluding accidental poisoning by other drugs or substances

Probability of adverse drug reactions

Reactions were classified as

Definite directly attributable to a drug having a clear temporal relationship to the time of administration and confirmed by positive rechallenge or laboratory investigation e g evidence of abnormal blood levels etc

Probable occurring with a clear temporal relationship to administration and improving on withdrawal of therapy

Possible having some temporal relationship to administration but the effects could have been due to the basic illness

Severity of adverse reactions

Reaction severity was classified as

1 Causing death
2 Life threatening—demanding immediate action to prevent death
3 Severe—necessitating the use of supportive therapy prolonging the patient s admission by 3 or more days or causing admission to hospital and resulting in either of the above
4 Moderate—necessitating the administration of an antidote or symptomatic treatment prolonging admission by 1–3 days or causing admission and resulting in either of the above
5 Mild—incidental in the patient s progress and not requiring treatment

Mechanisms of adverse reactions

To provide a classification of the mechanisms of adverse drug reactions which could be readily interpreted in the clinical situation a modification of schemes suggested by several authors was adopted (5 7 17 18)

Reactions were classified as

1 Intended effect excessive *(TOXIC)* *(a)* with overdosage (according to Clark s rule) *(b)* without overdosage (c) potentiation—possible additive effect of drugs with similar actions

Table 1 *Drug usage in paediatric patients*

Age group (years)	No of patient admissions	No not on therapy while in hospital	No of drugs prescribed in hospital	Average per patient

who suffered from viral respiratory infection and febrile convulsions Drug use was greatest in the oldest age group due to the relative fre quency of cardiac investigation and the treat *ment of malignancy in this group*

Phenobarbitone was the most commonly used drug (Table 3) but preparations with anti bacterial activity constituted the largest phar macological group comprising 469 (21 5%) of the prescriptions Anticonvulsant/sedatives were the next largest group and were followed in frequency by radiodiagnostic agents

The deployment of drugs for different pur poses in differing situations explains the rela tive frequency of barbiturate usage as these drugs were popular as basal sedatives for in vestigative procedures Five hundred and forty (24 7%) prescriptions were for drugs given to aid investigations and 108 treated patients received drugs for this purpose alone Thus of the total population 357 (38 3%) patients did not receive drug therapy directed at the cure or symptomatic relief of the disease causing admission

It was apparent that the pattern of prescrib *ing of British hospital practice differed from* that of general practice Table 4 illustrates the pre admission medication of a comparable group of children admitted to the same unit

Prevalence of adverse drug reactions

Adverse drug reactions were detected in 51 (6%) patients Thirty nine (6 5%) of 595 chil dren who received medication in hospital ex perienced at least one adverse reaction to therapy while 13 patients had reactions to

drugs prescribed by their general practitioners (Table 5) Twelve (10%) reactions caused admission to hospital and affected 12 patients The 51 affected patients experienced 119 adverse reactions of which 28 were definite 78 were probable and 13 were possible

Nature of adverse drug reactions (Table 6)

Gastro intestinal symptoms were the most frequent manifestations of adverse drug effects and together with skin disorders constituted 49% of the total The large number of haematological abnormalities is due to the frequency with which reactions occurred in patients receiving anti neoplastic therapy and the repeated laboratory tests which were performed on this group However these patients also exhibited clinically detectable reactions more frequently than did others

Mechanisms of adverse drug reactions (Table 7)

Unintended but predictable side effects were the most frequent adverse reactions to hospital therapy Allergic responses to drugs occurred with a frequency comparable to that recorded in other studies and were disproportionately represented in patients who experienced ill effects from their pre admission medication The high incidence of potentiation reflects the difficulty experienced in assessing the possible mechanisms of reactions by clinical means when the affected patient was subject to the simultaneous administration of several drugs with similar pharmacological properties

Drugs involved in adverse drug reactions (Table 8)

Although at least one adverse reaction occurred with eight of the ten most frequently prescribed drugs ampicillin caused more ill effects than any other single preparation In hospital however the anti neoplastic drugs

who suffered from viral respiratory infection and febrile convulsions Drug use was greatest in the oldest age group due to the relative frequency of cardiac investigation and the treatment of malignancy in this group

Phenobarbitone was the most commonly used drug (Table 3) but preparations with antibacterial activity constituted the largest pharmacological group comprising 469 (21 5%) of the prescriptions Anticonvulsant/sedatives were the next largest group and were followed in frequency by radiodiagnostic agents

The deployment of drugs for different purposes in differing situations explains the relative frequency of barbiturate usage as these

Table 4 *Pre admission drug usage (590 patients)*

Types of drugs	Number of drugs taken	% of total
Antibacterials	195	20 [illegible]

drugs were popular as basal sedatives for investigative procedures Five hundred and forty (24 7%) prescriptions were for drugs given to aid investigations and 108 treated patients received drugs for this purpose alone Thus of the total population 357 (38 3%) patients did not receive drug therapy directed at the cure or symptomatic relief of the disease causing admission

It was apparent that the pattern of prescribing of British hospital practice differed from that of general practice Table 4 illustrates the pre admission medication of a comparable group of children admitted to the same unit

Prevalence of adverse drug reactions

Adverse drug reactions were detected in 51 (6%) patients Thirty nine (6 5%) of 595 children who received medication in hospital experienced at least one adverse reaction to therapy while 13 patients had reactions to

Table 5 *Relationship of adverse reactions to time of detection and source of prescription*

	Reactions causing admission	Reactions present at admission	Reactions detected in hospital due to prior therapy	Reactions due to hospital therapy
Prescribed by general practitioner	8 (8)	1 (1)	4 (4)	0
Prescribed by hospital staff	4 (4)	12 (3)	0	90 (39)
Total	12 (12)	13 (4)	4 (4)	90 (39)

reactions In two cases this was made possible by effective treatment of the clinical effects of the reactions but in 68 (56%) reactions affecting 19 children the continuation of the treatment of the basic disease was of such importance as to prevent its alteration regardless of the severity of the adverse effects experienced In 41 of these reactions some form of symptomatic or supportive therapy was required

Treatment was given for the clinical effects of 61 adverse reactions On only 5 occasions was a specific antidote available and in the majority of cases the treatment was symptomatic Supportive therapy to prevent deterioration of the child s general condition was required on 23 occasions Despite the severity of a further 5 adverse reactions no treatment could be given as no appropriate therapy was available

Fifty three (44 5%) reactions did not require any treatment

DISCUSSION

Intensive drug surveillance has proved to be of particular value for the epidemiological investigation of adverse drug reactions as it has enabled workers to adopt a more general approach to the problem of drug induced disease The system can be used to detect previously unrecognised adverse drug effects as well as to investigate their prevalence and aetiology (11) and the comprehensive nature of the data generated by the method has allowed comparisons to be made between the drug usage and adverse reaction patterns of different countries (12)

Similar studies of paediatric patients have shown that the adverse drug effects experienced by sick children differ from those of adults and that the differences are attributable to the distinctive drug usage patterns of childhood (2 13) This study while confirming these findings has also shown that variations in the prescribing practices of different paediatric centres may alter the frequency with which reactions occur

Our patients received fewer drugs (0 26/patient/day) than did their American counterparts whose level of drug usage (0 44/patient/day) was similar to that of adults (1) Also the pattern of drug use was different symptomatic treatment being commoner in American children who often received the types of drugs prescribed by general practitioners in the United Kingdom For example it is of particular interest to note the wide use of aspirin

Table 8 *Drugs most frequently involved in adverse reactions*

Drug	No of adverse reactions	No due to possible potentiation	No of patients	Patients receiving same drug	Per centage
Prescribed in hospital					
Methotrexate	15	15	7	9	77

Metoclopramide	2	0	2	11	28
Triclofos	1	0	1	4	25
Diphenhydramine	1	0	1	7	14

were most frequently involved in adverse drug reactions reflecting the modern aggressive approach to the treatment of malignant disease and the lack of specificity of this drug group The types of drugs which caused adverse reactions before admission were completely different, however, and emphasised the frequent use of antibiotics and symptomatic preparations in general practice The overall risk to patients of these drugs could not be assessed due to the lack of complete and accurate denominator data

Factors predisposing to adverse drug reactions

Adverse drug reactions occurred most frequently in children who suffered from serious diseases which presented a difficult therapeutic challenge (Table 9) Seventeen patients with malignant disease (2% of admissions) constituted 33% of affected patients and experienced 77 (64 7%) adverse reactions Similarly patients in other categories often suffered from complicated disorders such as epilepsy with proven brain abnormality or pyelonephritis complicating structural renal defects These therapeutic difficulties may also be reflected in the demonstrable relationship between increasing drug usage and the number of adverse drug reactions experienced As in other studies we found that the number of reactions increased significantly when children received more than four drugs during their stay in hospital ($p=0\ 01$) We were, however unable to demonstrate any predisposition to adverse drug reactions by age or sex

Severity of adverse drug reactions and effect on management

During the study no deaths were directly attributable to the adverse effects of drugs but 2 (1 7%) adverse reactions were considered life threatening Twenty four (20%) reactions were severe 56 (47%) were of moderate severity and 37 (31%) were mild

Adverse drug effects caused therapy to be discontinued on 12 occasions but on 8 of these effective alternative preparations were administered A further 18 reactions necessitated some reduction of the dosage of the offending drug or drug combination Nineteen (16%) reactions occurred after the completion of a course of therapy and 7 of these required treatment for the resulting clinical effects

Thus the basic treatment of the underlying condition remained unaltered after 70 (59%)

Table 9 *Relationship of frequency of adverse reactions to diagnosis*

Disease	No of reactions detected	Percentage of total reactions (%)	No of patients experiencing reactions	No of patients with same diagnosis	Percentage of patients experiencing adverse reactions (%)

Fifty three (44 5%) reactions did not require any treatment

DISCUSSION

Intensive drug surveillance has proved to be of particular value for the epidemiological investigation of adverse drug reactions as it has enabled workers to adopt a more general approach to the problem of drug induced disease The system can be used to detect previously unrecognised adverse drug effects as well as to investigate their prevalence and aetiology (11) and the comprehensive nature of the data generated by the method has allowed comparisons to be made between the drug usage and adverse reaction patterns of different countries (12)

Similar studies of paediatric patients have shown that the adverse drug effects experienced by sick children differ from those of adults and that the differences are attributable to the distinctive drug usage patterns of childhood (2 13) This study while confirming these findings has also shown that variations in the prescribing practices of different paediatric centres may alter the frequency with which reactions occur

Our patients received fewer drugs (0 26/patient/day) than did their American counterparts whose level of drug usage (0 44/patient/day) was similar to that of adults (1) Also the pattern of drug use was different symptomatic treatment being commoner in American children who often received the types of drugs prescribed by general practitioners in the United Kingdom For example it is of particular interest to note the wide use of aspirin

in the USA while this drug was prescribed for only four of our patients

These variations of prescribing practice may in part explain why we encountered fewer adverse drug reactions Other paediatric studies have reported adverse reaction rates of 10–13 % with 3 % of patient admissions caused by adverse drug effects while in our experience drug induced disease (adverse reactions plus accidental poisoning) was responsible for 4 6 % of admissions but there were fewer reactions to hospital therapy (6 5 %) Reported prevalence rates for adults vary widely from 25–30 % in the United States and New Zealand to 10 6 % in Great Britain (7 12 14)

Thus the incidence of drug induced disease arising from the community was similar in both countries but fewer of our patients were affected in hospital Comparison of the available data suggests that this may have been due to three principal factors

(*a*) our practice of withholding antibiotic therapy from children with presumed virus infections

(*b*) infrequent use of symptomatic preparations

(*c*) and differences of approach to the treatment of serious disorders e g meningitis which may have minimised the exposure of our patients to drugs with a high incidence of side effects e g ampicillin

Despite the potential value of such comparisons in the epidemiological study of iatrogenic disease the clinical effects of adverse reactions on the patient and his progress must be appreciated if rational steps are to be taken to reduce their incidence The adverse effects produced must therefore be considered in relation to the severity of the basic disease and the efficacy of the treatment available thus producing a form of therapeutic audit (22)

In this study the majority of adverse reactions to hospital treatment occurred in patients with serious disorders and their clinical effects regardless of severity were frequently outweighed by the potential advantage of the basic therapy The high incidence of reactions to anti neoplastic therapy seen in both countries (13) must, therefore be balanced against recent improvements in the prognosis for patients with malignant disease (24)

On the other hand little is known about the prevalence of iatrogenic disease in the community or the therapeutic setting in which it occurs though recent studies (15) suggest that it may be a significant problem We considered that many of the reactions which caused admission to hospital could have been prevented and drug monitoring in that area may indeed be profitable Continued surveillance of out patients would also be desirable in view of the high incidence of adverse drug effects experience by adults after discharge from hospital (10)

Community based studies could well show that comprehensive drug surveillance in hospitals highlights only a small proportion of drug induced disorders and does so in a setting where little effective action can be taken to reduce the problem

ACKNOWLEDGEMENTS

We are grateful to Professor J H Hutchison for advice and to Mrs S Sweenie for computer analyses We also thank the medical nursing secretarial and pharmacy staffs for their willing co-operation This study was supported by the Higher Medicine Fund of the erstwhile Western Regional Hospital Board

CASE REPORT

FAMILIAL DYSAUTONOMIA IN A NON JEWISH CHILD

HARALD ØRBECK and GUNNAR OFTEDAL

From the Department of Paediatrics Rikshospitalet University of Oslo Norway

ABSTRACT Ørbeck H and Oftedal G (Department of Paediatrics Rikshospitalet University of Oslo Norway) Familial dysautonomia in a non Jewish child Acta Paediatr Scand 66 777 1977 —Few documented cases of Riley Day syndrome fulfilling current diagnostic criteria have been recognized in non Jews In our case the diagnosis was established in a Norwegian child despite the absence of Jewish origin It represents a report of this syndrome with bilateral pathological changes in the hypothalamus in addition to extensive abnormal findings in the spinal cord and the autonomic ganglia These findings may have significance with regard to the pathogenesis of the disease

KEY WORDS Familial dysautonomia

This paper reports a Norwegian child of non Jewish ancestry with Riley Day syndrome Necropsy study revealed pathological lesions in the spinal cord and autonomic ganglia in addition to slight changes in the hypothalamus and in some of the hypothalamic nuclei Riley (11) suggested in his original description of the syndrome that familial dysautonomia is an autosomal recessive disease and later investigations have verified this view (5) The striking and bizarre symptomatology points at dysfunction of the sensory and the autonomic nervous systems and includes diminished lacrimation hyperhidrosis transient skin blotching Other features are indifference to pain and diminished deep tendon reflexes whereas impaired temperature control and frequent vomiting may imply a hypothalamic involvement The loss of histamine flare response and the absence of fungiform papillae on the tongue are consistent findings (16) Pharmacologic physiologic and pathologic anatomic investigations have more sharply defined the clinical entity (2 5 15) but the basic mechanism of the disease remains unknown

CASE HISTORY

The infant K A P born November 1968 was the first child of Norwegian parents Two siblings are healthy The infant was delivered 4 weeks preterm with a birthweight of ?480 g During the first year the child regurgitated constantly Walking was delayed beyond the second year of age the gait was awkward and atactic and for moving around he preferred to use a tricycle Many burn injuries were incurred Excessive night sweating and frequent vomiting were prominent features Prior to these episodes pronounced drivelling and nausea occurred with skin blotching Feeding was slow and accompanied by regular spluttering Recurrent bouts of pneumonia developed as well as a number of unexplained episodes of fever

From four years of age repetitive vomiting crises occurred which necessitated hospitalization for rehydration Clinical evaluation showed absent deep tendon reflexes hypolacrimation anisocoria and absence of corneal reflexes The child's sensation to pain and temperature on legs and arms was diminished but seemed intact on the abdomen Visual inspection of the tongue which was uniformly smooth revealed lack of fungiform papillae The histamine flare response was absent Ocular instillation of ? 5% methacholine induced *miosis* Most of his final year was spent in hospital with repeated episodes of vomiting and aspiration pneumonia *fluctuating* temperature and vasomotor instability Chlorpromazine treatment appeared to alleviate the child's apprehension and initially gave some *symptomatic* relief However subcutaneous injection of the parasympathomimetic agent Bethanechol and later the anticholinesterase drug Pyridostigmine bromide over prolonged periods did not

Fig 1 Diffuse astrogliosis in lateral hypothalamic area (arrows)

Fig 3 Atrophy of the posterior fasciculi in the spinal cord

reveal any beneficial effects In fact his condition worsened as his vomiting attacks became more severe In addition the boy was afflicted by recurrent episodes of pneumonia Despite postural drainage and administration of broad spectrum antibiotics he continued to develop respiratory distress and arterial hypoxia Assited ventilation eventually became necessary The child died in the terminal complication of heart failure and hypoxia at an age of eight years his weight was 20 kg and height 118 cm

Neuropathological examination

The brain weight was 1190 g which is at the lower range of normal The gross inspection of the brain revealed nothing abnormal except a thin corpus callosum and a slightly rounded shape of the posterior part of the 3rd ventricle

Microscopy from representative areas of the brain was performed The only irregular features were observed in the hypothalamus where subependymal glial granulations protruded from the posterior parts of the walls A diffuse astrogliosis was present around small vessels and also scattered in the lateral hypothalamic area and in the ventromedial thalamic nucleus (Fig 1) The nerve cells in the paraventricular (Fig 2) and supraoptic nuclei showed unusually large vacuoles in their cytoplasm Counting of cells in this area was not performed so the impression gained of a decrease in number of nerve cells in the area could not be supported

In the spinal cord a marked demyelination and atrophy was observed in the posterior fasciculi (Fig 3) The nerve cells in the column of Carke (Fig 4) appeared reduced in number and partly also atrophic The intermediolateral cell column appeared normal

Fig 2 Large vacuoles in nerve cells in the paraventricular nucleus

Fig 4 Unsymmetrical atrophy of the column of Clarke

Fig 5 Spinal ganglion showing disappearance of neurons and residual nodules of Nageotte (dark cell clusters)

The spinal ganglia were difficult to locate because of their small size The ganglion cells had completely dis appeared leaving residual nodules of Nageotte to indicate their location (Fig 5) Some lymphocytic infiltration was present and the nerve fibers were atrophic

Sections from muscles in the lower and upper extremi ties showed unspecific atrophy probably due to inactiv ity

Finally the lacrimal glands were small and firm with increased connective tissue and scattered as well as peri ascular lymphocytic infiltration

DISCUSSION

Occasional involvement of the autonomic nervous system has been described in many neurological conditions Among specific dys autonomias perhaps the best known is the Riley Day syndrome a congenital progressive familial dysautonomia in which clinical re covery does not occur At the age of five years our patient displayed all cardinal symptoms and signs so far described and fulfilled all the criteria listed by Riley & Moore (12) A section from the dorsum of the tongue failed to reveal any fungiform papillae The diagnosis was confirmed by a positive intradermal histamine test (14) The term familial dysautonomia was originally applied to Jewish children with an unusual symptom complex extensively de scribed by Axelrod et al (4) The disease ap pears to have propagated by an autosomal re cessive mode of inheritance through the cus tom of intermarriage among Jews Few in stances of familial dysautonomia in non Jews have been reported However in the present case both parents were of Norwegian descent A close investigation revealed that no mar riage with Jewish individuals had occurred Until 1851 Jews were not granted admission to the country of Norway

A disorder of catecholamine release has been proposed as a possible pathogenetic mechanism in the Riley Day syndrome In general an elevated urinary HVA/VMA ratio has been reported (18) and in 25% of the cases a low level of serum dopamine β hy droxylase activity has been found (20) On the other hand one recent survey (7) reports no difference in serum dopamine β hydroxylase activity between 34 familial dysautonomia patients and a control population None of the above chemical findings were made in this case in spite of repeated tests Evidently such assays are not indispensable for the diagnosis of familial dysautonomia

The basic defect in familial dysautonomia is currently obscure Among previous explana tions nerve dysfunction involving acetyl choline activity has been put forward since parasympathetic insufficiency is the most striking clinical finding This would imply a defect in either acetylcholine synthesis or in the mechanism for its storage or release (9) The possibility of a receptor malfunction also arises and Drachman (6) suggests that acetyl choline may somehow mediate the trophic in fluence of the nerve It has been argued that a decreased number of unmyelinated fibres in peripheral nerves reported in several in stances (2 9) implies that peripheral nerve dysgenesis may be the underlying cause Siggers et al (13) found elevation of nerve growth factor in serum from patients with familial dysautonomia and proposed a poten

tial relation between Riley Day syndrome and this protein but so far there is no evidence to substantiate or refute this hypothesis

Though the diverse manifestations of this disease seem to suggest a central cause no consistent brain abnormality has been reported Sparsity of myelinated fibres in the dorsal roots and a symmetric degeneration of fasciculus interfascicularis in the dorsal spinal tract appear to emerge as the most characteristic neuropathologic manifestations of the disease (19)

In our case the brain weight was at the lower normal level and corpus callosum appeared thin The subependymal granulations in the walls of the posterior hypothalamus indicated some slight damage to the ependymal cells and the slight gliosis observed in the lateral parts of the hypothalamus and in the ventromedial thalamic nucleus pointed in the same direction The striking vacuolation of the nerve cells in the paraventricular and supraoptic nuclei may be regarded as an indication of hyperactivity in these cells The scattered observations made in the brain—although limited to the hypothalamic area—do not give conclusive clue regarding the nature of the basic disturbance in this disease

The initial report of the syndrome by Engel & Aring (3) presented before the syndrome had been named showed somewhat similar abnormalities Their finding of a thalamic cyst may not have been a coincidental lesion but a result of degenerative alterations on the basis of the same changes found in our patient The central manifestation noted in this case and the inconsistency of pathological findings described may be due to some metabolic change which also could be the answer to the cyclic nature of the disease

Although recent reports indicate improvements in survival life remains a struggle for these children and their families It should be noted however that despite the rarity of the disease a parent organization is founded in the United States in an effort to find help and hope for these handicapped children

CASE REPORT

MONOZYGOTIC TWINS CONCORDANT FOR TRACHEO ESOPHAGEAL FISTULA AND DISCORDANT FOR THE VATER ASSOCIATION

SUSANNE L KING R L LADDA and S J SHOCHAT

From the Departments of Pediatrics and Surgery the Pennsylvania State University College of Medicine Hershey Pennsylvania USA

ABSTRACT King S L Ladda R L and Shochat S J (Departments of Pediatrics and Surgery Pennsylvania State University College of Medicine Hershey Pennsylvania USA) Monozygotic twins concordant for tracheo-esophageal fistula and discordant for the VATER association Acta Paediatr Scand 66 783 1977 —Monozygotic female twins were concordant for tracheo-esophageal fistula (TEF) and one twin also manifested other anomalies of the VATER association including agenesis of the female reproductive tract Review of the literature discloses a familial tendency for recurrence of TEF and a high concordance rate in monozygotic twins indicating a significant genetic influence for the isolated anomaly In the case of the VATER association the sporadic occurrence of affected individuals and discordance in twins implicates the effect of non genetic factors

KEY WORDS Tracheo-esophageal fistula VATER association *monozygotic twins female genitalia*

Tracheo-esophageal fistula (TEF) may occur as an isolated anomaly or associated with one or more defects Quan & Smith (14) noted that certain of these anomalies occurred together more frequently than expected by chance alone and they proposed the acronym VATER to denote the apparently non random association of vertebral anomalies anal atresia TEF and renal and/or radial dysplasia More recently malformations of the male external genitalia have been described as part of this association of anomalies (1) We wish to report a case of monozygotic female twins who were concordant for tracheo esophageal fistula One twin also exhibited anomalies characteristic of the VATER association as well as agenesis of the female reproductive tract A similar combination of malformations in twins has not been reported previously

CASE REPORT

Monozygotic female twins were born at approximately 32 weeks gestation to a mother in good health Zygosity of the twins was established by examination of the placenta it had a single chorion and a single amnion The pregnancy was complicated by polyhydramnios Both twins were cyanotic at birth and required intubation and positive pressure O_2 Several hours after birth the twins were found to have TEF and they were transferred to our medical center for care

Twin A weighed 1360 g at birth physical examination revealed no abnormalities An X ray study revealed a blind upper esophageal pouch consistent with the diagnosis of TEF with esophageal atresia (Type C) Skeletal X rays intravenous pyelogram (IVP) and electrocardiogram (ECG) revealed no further abnormalities

Twin B weighed 1 00 g and was noted to have an imperforate anus with a fistula to the vulvar area and no vaginal orifice X ray study also revealed a blind esophageal pouch confirming the diagnosis of TEF with

esophageal atresia (Type C) Skeletal X rays disclosed two left hemi vertebrae and fusion of two pairs of ribs in the right thorax IVP showed an ectopic midline pelvic kidney with a single ureter ECG was normal This infant died after three months and autopsy revealed agenesis of the fallopian tubes uterus and vagina The karyotype was normal

DISCUSSION

Six sets of twins concordant for TEF have been reported (4 5 7 11 19) In five twins in which zygosity was determined four were monozygotic and one set was dizygotic Although isolated TEF generally has been a sporadic occurrence in an otherwise normal family it has recurred in families most often in the offspring of normal parents (8 10 17) Engel et al (10) described TEF in a mother and her child and Schimke et al (17) found five members of one family affected In contrast individuals considered to have the VATER association (3 or more defects) have all occurred sporadically (1 14 18) In one family TEF and imperforate anus occurred in three siblings of normal parents (12) but no other defects were noted In only one other instance has the VATER association occurred in twins and as in our case only one twin was affected (18) Thus TEF is associated with a definite familial tendency whereas the VATER association is not

Barry & Auldist (2) reported that 43% of their patients with TEF had at least one other major abnormality the most frequently occurring being those of the VATER set of anomalies They suggested that the VATER association should be considered as part of a spectrum that ranges from the occurrence of one defect alone such as TEF to the full set of VATER anomalies However instances of the VATER association have all been sporadic and with the exception of our monozygotic twins, we are unaware of the occurrence of isolated TEF and the VATER association in near relatives On the other hand isolated TEF is associated with a familial tendency This suggests that the etiology of isolated TEF may differ from that of TEF occurring with the VATER association

Isolated TEF is estimated to occur from 1 in 800 to 1 in 2 500 live births (3 13) The familial tendency for TEF (simulating autosomal recessive and dominant inheritance patterns) and the increased occurrence in near relatives (monozygotic twins siblings and offspring) compared to the general population suggests a multifactorial mode of heritability (6) Applying Edwards (9) empiric formula ($\sqrt{\text{population incidence}}$) an estimate of the recurrence risk of TEF in first degree relatives may range from 2–3 5% i e 25–50 × greater risk than the general population Because of this increased recurrence risk with the economic and psychological burden associated with the surgical correction and long range treatment of TEF prenatal diagnosis (amniography) may be offered in subsequent pregnancies Contrast material injected into the amniotic fluid is swallowed by the fetus outlining the gastrointestinal tract and permitting the diagnosis of TEF (15)

The occurrence of genital anomalies with the VATER association is a recent observation (1 18) Genital malformations noted by Apold et al (1) in 3 of 7 male patients with the VATER association included bifid scrotum dysplastic penis and hypospadius with testicular atrophy They also called attention to earlier reports of hypospadius and female pseudohermaphroditism in other patients with the VATER set of anomalies (16 18) In twin B the female reproductive system was completely absent not even the external vaginal orifice was present The severity of this defect in our patient suggests a total failure of Mullerian differentiation

CASE REPORT

TRISOMY 20 MOSAICISM

X CARBONELL M R CABALLIN A RUBIO and J EGOZCUE

From the Department of Neonatology Instituto Corachan and the Instituto de Biologia Fundamental Universidad Autonoma de Barcelona Barcelona Spain

ABSTRACT Carbonell X Caballin M R Rubio A and Egozcue J (Department of Neonatology Instituto Corachan and Instituto de Biologia Fundamental Universidad Autonoma de Barcelona Barcelona Spain) Trisomy 20 mosaicism Acta Paediatr Scand 66 787 1977 —The first known case of trisomy 20 mosaicism is described As in other cases of (partial) trisomy 20 the patient showed scarce physical malformations It is suggested that trisomies for chromosomes of the F group are rare not because they are lethal but as a result of the morphology of the chromosomes involved

KEY WORDS Trisomy mosaicism chromosome 20

According to Sandler & Hecht (5) trisomy 19–20 is rare in spontaneous abortions and unknown in live births In the pre banding era several cases of partial F trisomy were published (1 4) but in all of them the chromosomes were identified by morphology alone Carrel et al (2) using autoradiography identified one case of partial F trisomy resulting from a familial F/13 translocation More recently Šubrt & Brychnač (6) described one case of trisomy for the short arms of chromosome 20 using banding techniques this case of partial trisomy was due to a 20/21 translocation

In this paper we report a case of regular trisomy 20 mosaicism identified by G banding techniques

CASE REPORT

The patient was an 8 month-old Caucasian male born to unrelated parents He was seen by the pediatrician due to a persistent anorexia The physical examination revealed a well developed pale obese child with a slight turricephala mongoloid slant of the eyes and internal epicanthus A simian crease was present in the right hand All other studies performed were normal

CYTOGENETIC STUDIES

The examination of Giemsa stained slides from routine blood cultures revealed the presence of two cell lines one with 46 chromosomes (60%) and the other with 47 chromosomes (40%) The extra chromosome seemed to belong to the F group

G bands were obtained using a technique described by us (3) According to its banding pattern the extra chromosome was identified as a no 20 (Fig 1)

DISCUSSION

To our knowledge this is the first confirmed case of regular trisomy 20 mosaicism The main interest of the case resides in the fact that none of the two cases confirmed by banding techniques (one partial one mosaic Šubrt & Brychnac (6) and present case) resulted in severe malformations In the case of Šubrt & Brychnáč the child had a mild mental subnormality epicanthus arched palate maxillary hypoplasia spondylodysplasia thoracic kyphosis and lumbar lordosis In our case the signs were so minimal that neither the obstetrician nor the parents had paid any attention to them This suggests that trisomy 20

ANNOUNCEMENT

DR HEINZ KARGER PRIZE

The prize which is awarded every year in memory of Heinz Karger the wellknown Basle publisher for an out standing scientific work has in 1977 been conferred in equal parts to *R J Gates and H R La arus* (England) for their paper The Ability of Pancreatic Polypeptides (APP and EPP) to Return to Normal the Hyperglycaemia Hyperinsulinaemia and Weight Gain of New Zealand Obese Mice and *Thomas Krieg and Peter K Muller* (Germany) for their paper The Marfan s Syndrome In vitro Study of Collagen Metabolism in Tissue Specimen of the Aorta

The Dr Heinz Karger Memorial Foundation invites the submission of papers on the following subjects

1978 An original research paper on Cytological and Histochemical Approach to the Diagnosis of Tumors

1979 An original research paper on Endocrine Mechanisms in the Pathogenesis of Essential Hypertension

Conditions Manuscripts shall not exceed 20 type written pages including illustrations tables and bibliography Manuscripts marked Competition must reach the publishers S Karger AG Arnold Bocklin Strasse 25 CH-4011 Basle (Switzerland) not later than February 28 1978 and 1979 The manuscript must be typewritten on one side only double spaced and is to be submitted in quadruplicate and in accordance with the instructions contained in the Rules for the Preparation of Manuscripts This leaflet can be obtained free of charge from the publishers if the request is marked Competition

Language English German or French

Publication The winning papers will be published in English in one of the Karger journals

The award for the prize will be SFr 7000 00

The Council of the Foundation will judge the papers and confer the prizes

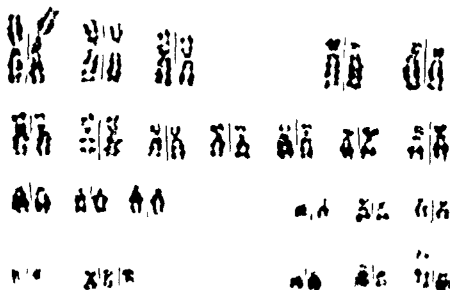

Fig 1 G banded karyotype showing trisomy 20

may not have an extreme deleterious effect as was previously thought It is possible that trisomies of the F group are scarce not because they are nonviable but due to the fact that the morphology of the chromosomes (metacentric) by regularly producing two chiasmata during meiosis I prevents their precocious separation and non disjunction

J C Somogyi & Tashev (eds) *Early signs of nutritional deficiencies* 173 pp illus Proceedings of the 13th Sym posium of the Group of European Nutritionists Sofia and Varna May 8-31 1974 Bibliotheca Nutritio et Dieta No 23 S Karger Basel 1976 sFr/DM 98 — ISBN 3 8055 2314 9

The lectures from the 13th Symposium of the Group of European Nutritionists in 1974 are now available in book form To detect slight deficiencies in the metabolism of protein EFA vitamins minerals or trace elements methods are needed for an early diagnosis A revue of early clinical and biochemical signs of protein calorie malnutrition (PCM) is given in the book It is now pos sib e to select those children or those groups of children who are at risk of developing PCM

Malnutrition following gastric resection depends in part on morphologic and especially on enzymatic deficiencies of the intestinal mucosa Lactase and other disaccharidase deficiencies underlie the impaired digestion and absorp tion of milk and carbohydrates Clinical and chemical diagnostic signs of polyunsaturated fatty acid deficiency are given An impaired platelet function and other hema t logi al disturbances in essential fatty acid deficiency are of great interest Food deficiency diseases and the en zymatic adaptation to protein deficiency are presented and termed diseases of imbalances of nutrition at the cellular level

Good analytical methods are now available for measur ing vitamin A E thiamine (transketolase activity) and the niacin metabolite (N methyl nicotinamide) The advan tages and disadvantages of different radioisotopic meth ods in the diagnosis of vitamin B ₁ are discussed The lec tures con erning iron deficiency are of minor interest The commonly used parameters have een applied on dif ferent pc pulation groups Evaluati n of the methods used i lacking and no l nes for the future are given Aspects of e g ferritin-determinat on iron isotop techniques and wh le body counting are mi sing

In the chapter f cal ium and phosphorus deficiency the tatements by FAO/WHO in 1962 are referred to no lear-cut disea e due to cal ium deficiency has ever been described At pre ent no single biochemical test can be used f r the early diagnosis of trace-element (Zn Cr Cu) defi ency in man The most promising line will be the ssay of mi r element-dependent enzymes

In on lus n the boo k is of interest for all working with nutriti nal pr blems The results of the symposium h d been more useful if the editors had included the dis u ns and if the chairmen had summarized each se tion

F A Hommes & C J van den Berg (eds) *Normal and pathological development of energy metabolism* 246 pp illus Academic Press London New York San Francisco 1975 £7 50

This book is the result of a meeting on the relation be tween developmental biochemistry and inborn errors of metabolism associated with brain damage held in the Netherlands in October 1974 The volume contains 18 presentations held by invited specialists in pediatrics biochemistry and genetics The success of this inter disciplinary approach is evident from the included stimulating discussion following each presentation The papers are uniformly of a high quality and summarize recent research data of basic character that could not easily be collected from their sources

Introductory papers deal with energetic aspects of late fetal and neonatal metabolism factors influencing growth and differentiation of the embryonic rat pancreas hor monal regulation of enzyme synthesis and the influence of food on body composition of low birth weight infants Developmental changes in carbohydrate metabolism that occur in the rat liver are discussed in two articles and evidence is presented showing that the rate of gluconeo genesis from lactate is higher in the infant as compared to the adult animal whereas the contribution of the alanine cycle to gluconeogenesis is low during the neonatal period Another interesting contribution describes the effect of ammonia on metabolic processes in isolated liver cells addition of ammonium chloride increased the energy demand of the cells and it was suggested that this observation could contribute to the understanding of ammonia toxicity Other papers deal with biochemical changes in diseases caused by inborn errors of metabo lism such as galactosemia fructose intolerance phenyl ketonuria Maple syrup disease and a more recently described condition with deficiency of hepatic methionine adenosyltransferase

A series of papers concern substrate utilization in the developing brain The high utilization of ketone bodies by the brain during growth is discussed by different authors including Land and Clark who suggest that ketone bodies are important as substrate for both synthesis and energy production in the developing brain In a succeeding paper Clark and Land also present data which indicate that the transport of both pyruvate and 3 hydroxybutyrate into the brain mitochondria can be inhibited by phenylpyruvate and 2 oxo-4 methyl pentanoate Based on these observations the authors suggest that an inhibited transport of pyruvate and 3 hydroxybutyrate into the mitochondria could in part ex plain the defective myelination and depressed energy metabolism seen in phenylketonuria and Maple syrup disease Finally Blass and co-workers have written a very helpful review on the clinical and metabolic abnormalities which accompany deficiencies in pyruvate oxidation

This book covers a wide range of topics It might there fore have been helpful if the papers had included a brief summary and if the different articles had been arranged under different headings The book should be of interest for pediatricians with special interest in inborn errors of metabolism and developmental brain biochemistry

BOOK REVIEWS

J F Bosma & J Showacre (eds) *Symposium on development of upper respiratory anatomy and function Implication for sudden infant death syndrome* U S Department of Health Education and Welfare Publication No (NIH) 75 941 Washington D C 1975 279 pp illus $7 10

Sudden unexpected infant death (SID) continues to be a challenge to medical research The incidence appears too low to permit rational longitudinal population studies with the purpose of early detection of factors to identify infants at risk but is far too high to be regarded as just a sad curiosity Although the number of proposed causes is large and increasing much interest has lately been focused on the possible role of reflexes elicited from the upper airways The proceedings of this symposium held in 1974 are consequently of great interest The list of distinguished participants reveals the aim of the organizers to stimulate an interdisciplinary discussion at a high level

An interesting introductory chapter deals with the anatomy of the upper respiratory tract in the newborn in relation to its positional respiratory and feeding functions and to their postnatal development Illustrations are numerous and informative Aspects of the embryology of the region are presented with special attention given to the neural crest in a following chapter Large space is devoted to a paper on the mechanics of the larynx in adults but due to well known anatomical differences its relevance to infants is doubtful The distribution of blood and lymph vessels in the region is demonstrated with interesting lymph vessel connections between the palate and the pharynx The morphological section is ended by a well illustrated paper on the development of sensory receptors in oral mucosa Morphology has hitherto given few clues to the riddle of SID One serious problem is that present knowledge of normal variations in upper respiratory tract anatomy in infants is far from complete

The development of the control of respiration is a wide and rapidly progressing field An up to date review would have been more appropriate than the paper presented which partly deals with lung mechanics and includes some puzzling information The reference list ends at 1967

Some excellent papers are devoted to the induction of apnea in animals by stimulation of sensory receptors in the upper airways and in the larynx Recent work has revealed receptors which respond to water and to milk from other species This may represent a breakthrough in SID research as animal models are now available to study a physiological process which may be significant in human SID The possibility that SID victims are hyporesponders to respiratory stimuli is also discussed in an interesting paper and methods for testing this are presented in another one

The value of the book is further increased by reports from sometimes animated discussions of the papers and extensive indices of authors and subjects

Ola Hjalmarson

D A Fisher & G N Burrow (eds) *Perinatal thyroid physiology and disease* Kroc Foundation Series No 3 Raven Press Publishers New York 1975 277 pp illus US $20 95

The recent availability of highly sensitive and specific radioimmunoassay systems for measurement of thyroid hormones and TSH in biologic fluids has dramatically changed our understanding of thyroid physiology and disease Screening of newborn infants for congenital hypothyroidism has also become possible Thyroid hormone deficiency may at critical periods of human development severely limit central nervous system maturation To date it is not known with certainty whether early treatment will prevent mental retardation Because congenital hypothyroidism may occur as frequently as 1 in 5000 births the answer to this question is of extreme importance to the patient as well as to the parents and to society

This book gives an excellent review of present knowledge regarding these problems The first part concerns with normal thyroid physiology in both the mother and the foetus The second part deals with experimental studies on thyroid hormone in development with special reference to the central nervous system The third part concerns with thyroid disease in pregnancy and the newborn including treatment of and prognosis for children with congenital hypothyroidism treatment of thyrotoxicosis during pregnancy and a review of congenital Grave s disease In the last part of the book several contributors report on their experiences of newborn screening for hypothyroidism using various methods at various times during the neonatal period The results constitute a valuable base for future screening programs for congenital hypothyroidism

Berta Bobath *Abnorme Haltungsreflexe bei Gehirnschaden* 3rd ed 94 pp illus Georg Thieme Verlag Stuttgart 1976 DM 9 80 *ISBN 3 13-4351-03 X*

This book is a new edition of the German translation of the now classic work of Berta Bobath on abnormal postnatal reflex activity It was first published in English already in 1954

There is a short introduction by Mrs Bobath and the small volume is well illustrated with instructive pictures

ACTA PÆDIATRICA SCANDINAVICA

VOL 66 1977

Alternative approaches to meeting basic health needs in developing countries V Djukanovic & E P Mach (eds) World Health Organization Geneva 1975 116 pp sFr 24 – ISBN 92 4 156047 7

This volume is the report of a study carried out jointly by UNICEF and WHO in 1973 and 1974 Faced with the failure of conventional health services to make an impact on the health problems of developing countries the two organizations decided to examine some of the successful or promising primary health care systems now operating in these countries in an attempt to pick out the factors responsible for their success

Part I of the report describes the underprivileged sections of the population who are often without even rudimentary health services While remedies are available for many of the shortcomings they often cannot be applied without changing the whole concept of health care

Part II presents descriptions of 10 successful or promising innovative health care programmes in different parts of the world There are programmes adopted nationally and those covering more limited areas

In part III of the report the editors draw a series of conclusions Despite the immense problems it is possible using the resources available to meet some of the people s basic health needs In the national programmes one of the crucial features has been a strong political will for change In the more local schemes enterprise and leadership have been vital

On the basis of the report WHO and UNICEF have taken decisions implying major changes in their own policies

The booklet is a fascinating reading for anyone concerned with health needs priorities and policies The examples of achievements reached by human involvement and leadership are far greater than most of us would ever dream of

The issues concern us much more than appears from the title How should self reliance in health be interpreted in various cultural and economic situations? How does one get community motivation and continuous participation in solving the health needs of any society? How should the patients right to democratic influence in the health care process be balanced against political democracy?

The studies presented in this volume could be regarded as a take off point for a new global strategy on health

J M Tanner R H Whitehouse W A Marshall J R Healy & H Goldstein *Assessment of skeletal maturity and prediction of adult height (TW2 Method)* pp illus Academic Press Inc London New York San Francisco 1975 £9 00

In 1962 Tanner Whitehouse & Healy published the method for assessment of skeletal maturity (TW1) Each bone of the hand and wrist was given a score depending on its development The sum of these scores formed an expression for the skeletal maturity This publication presents a revised version of the original method The previously used scoring system is retained essentially unchanged However the different scoring points have been recalculated according to a more valid mathematical and statistical model

The system furthermore provides separate maturities for 1) the carpal bones 2) the distal epiphysis of radius and ulna the metacarpals and phalanges (RUS) and 3) all the bones of the hand and wrist The RUS maturity is most valid in the prediction of adult height which is one of the important applications extensively discussed by the authors Another one is the correlation between the effect of different hormones and skeletal maturity

In everyday clinical work the TW2 method is as time consuming as the TW1 method was The method is of importance especially in assessment of skeletal maturity in patients with irregular development of the different bones in the hand and wrist

The prediction of adult height according to the present method has theoretical advantages as it takes into consideration 1) added residual standard deviation and 2) parental heights In practical situations the method gives values comparable to those of other methods As a research tool the TW2 method is ideal and the book ought to be available in every department where skeletal maturity is routinely assessed

Preparation of Manuscripts

ntributors are requested to pay particular attention the following rules governing the preparation of nuscripts *Failure to follow these rules is a frequent use of delay in the publication of articles and may ult in rejection of otherwise acceptable manuscripts*

Manuscripts should be sent, in duplicate to the fice of the Managing Editor Professor C. G Bergrand, Department of Paediatrics Malmö Allmänna ukhus S-214 01 Malmö Sweden mailed flat and ansmitted by first class mail They should be double-aced typewritten on one side of the paper with wide argins Authors should exercise particular care in e preparation, notation and description of figures d tables Each table must be accompanied by a escriptive title typed above the table to which it efers A suitable legend must be provided for each igure Oversized original illustrations should be hotographed and a print on *glossy paper submitted* A separate *title page* is necessary and should bear) the title b) the initials and names of the authors) the institution of origin Below the list of *references* he principal author should state his address to which he proofs are to be sent

A short *abstract* not exceeding 200 words must ccompany each manuscript informing about problem, methods results and conclusions Unexplained bbreviations and references are not allowed The bstract must be typed on a separate sheet and styled s illustrated

ABSTRACT Köhler L. and Holst K. (Department of Paediatrics, University Hospital, Lund Sweden) Dental health of four year-old children Acta Pædiatr Scand 00

An unselected population of 1 567 four year-old children

KEY WORDS Pre-school children caries gingivitis

A *summary* is usually not necessary but may be allowed if the author (or the Editor) finds it essential A summary should be typed immediately after discussion"

References to the literature should be limited to those quoted by the author The reference list should be arranged alphabetically and numbered, giving name of author (authors) initials full title of paper name of journal abbreviated in accordance with the style of *Index Medicus* (*New Series*) followed by the volume number page number and year *In this system of abbreviation periods are omitted.*

1 Brecher G & Stohlman F., Jr Humoral factors in erythropoietin. *In* L. M Tocantins & R. Penn (eds.) *Progress in hematology* Grune & Stratton, New York *1959 p 110*
2. Smith, C. A. *The physiology of the newborn infant* Thomas, Springfield, Ill 1967 3rd ed. vol 2, p 120
3 Vedra, B & Ulrych, J. Anaerobiosis in normal and asphyxiated premature newborns. 2. Four approaches. *Acta Paediatr Scand 49* 129 1960

Italics are marked in the manuscript by underlining

Abbreviations must conform to accepted standards. When in doubt authors are advised to consult a recent issue of the journal The SI system should be used Laboratory slang, clinical jargon and colloquialisms must be avoided

Proofs and Reprints Galley proofs will be sent to *the principal author* by the printer The master proof should be returned to the Managing Editor together with the manuscript within three days and by air mail if received by air mail Reprints of articles published must be ordered by separate application from *Almqvist & Wiksell S 751 81 Uppsala Sweden* to whom cheques money orders and drafts should be *made payable*

Manuscripts books for review and correspondence relating to the editorial management should be sent to the Managing Editor Department of Paediatrics Malmö Allmänna Sjukhus, S-214 01 Malmö Sweden. Published manuscripts are not returned *unless requested*

SERUM IMMUNOGLOBULIN LEVELS IN THE COURSE OF ANAPHYLACTOID PURPURA IN CHILDREN

S SIMILA K KOUVALAINEN and M LANNING

From the Department of Paediatrics University of Oulu Oulu Finland

ABSTRACT Simila S Kouvalainen K and Lanning M (Dept of Paediatrics University of Oulu Oulu Finland) Serum immunoglobulin levels in the course of anaphylactoid purpura in children Acta Paediatr Scand 66 537 1977.—Serum levels of immunoglobulins (IgG IgA IgM IgD and IgE) were determined at frequent intervals in the course of anaphylactoid purpura (AP) in children AP was cured without complications in 16 out of 26 cases recurring in 7 cases Melena was manifested in 9 cases and nephropathy in 5 The levels of IgA and IgM were elevated in AP but serum IgG IgD and IgE showed no significant changes The serum level of IgM was significantly ($p<0.0125$) higher in patients with AP nephropathy than in those with recent AP The elevated serum IgA and IgM levels are possibly related to the pathogenesis of AP and/or its renal involvement

KEY WORDS Anaphylactoid purpura immunoglobulins nephropathy

The cause of anaphylactoid purpura (AP) an allergic vasculitis of childhood manifested by a characteristic skin rash and often also associated with arthritis gastrointestinal symptoms such as pain and melena or glomerulonephritis has remained unknown Histologically the skin (1) and renal lesions (10 19) in AP resemble those in certain immune complex diseases Selective elevation of serum IgA has been reported in most patients with AP (8 15 16)

In order to check the immunological response in children with anaphylactoid purpura serum immunoglobulin levels were determined several times in the course of the disease and the elevation of the serum IgA and IgM levels followed High IgM was associated with AP nephropathy

MATERIAL AND METHODS

St d up

Th dy group cons sted of 6 children 11 female and 1 with anaphylactoid purpura treated in the Department of Paediatrics University of Oulu during the 3 year period 1973–75 The basic criterion for including a patient in the study group was purpuric rash characteristically affecting mainly limbs and buttocks Other diseases with similar manifestations were excluded A history of infection occurring during the 4 weeks preceding AP was present in 77% of the children and evidence of streptococcal aetiology (positive culture elevated AST titre) was recorded in 5 patients Two of the patients had a history of allergy (atopic excema allergic rhinitis or bronchial asthma)

In the course of the disease serial determinations of serum immunoglobulins IgG IgA IgM IgE and IgD were performed varying in number between 2 and 6 The patients were divided into four subgroups according to the outcome of AP as follows (Fig 1)

1 patients with simple AP without any complications (all cured at the first attempt)
2 patients with AP and melena
3 patients with recurrent AP
4 patients with AP and nephropathy

Methods

The serum levels of IgG IgA IgM and IgD were determined by the single radial immunodiffusion method of Mancini (12) using commercially available antisera from Behringwerke The concentration of IgE was determined by a radioimmunosorbent technique ((9) commercial antiIgE antiserum from Pharmacia Uppsala) The accuracy of the methods was about ±10%

ent results that this elevation is independent of the severity of AP or any relapses or com plications occurring After long term recovery the high IgA level will be normalised (8) The cause of the elevated IgA is unknown It has been suggested that a local IgA antibody re sponse in the gastrointestinal tract might oc cur in AP and result in the increased serum IgA globulin levels (16) as Immonen (7) and Savilahti (14) have nicely demonstrated to oc cur in celiac disease It has been demonstrated in skin and rectal biopsies from patients with AP that vessel walls and dermo-epidermal junctions are particularly prone to contain de posits of IgA complement C3 and fibrinogen but there may also be some containing IgG and IgM (2 17)

The present results also indicate that the level of serum IgM is elevated in patients with recent AP and that it is obviously high in patients with AP nephropathy (Table 1) The main types of glomerular lesions in AP neph ropathy are minimal lesions diffuse endocapil lary proliferation focal and segmental glo merulonephritis membranoproliferative glo merulonephritis and endo- and extracapillary glomerulonephritis Deposits of immunoglobu lins mainly IgA C3 and fibrinogen but also IgM and IgG have been observed within the mesangium and also along the glomerular cap illary walls (13) In this respect AP nephro pathy resembles idiopathic mesangial IgA glo merulonephritis or Berger s disease (4) Pa tients with Berger s disease have elevated serum IgA levels but normal serum levels of IgM and IgG (11) It is suggested that in Berger s disease C3 is most probably activated by the alternate pathway possibly by aggre gates of IgA It is possible that the same al ternative pathway is also activated in AP by aggregates of IgA and IgM (5) It has also been noted in experimental animals that humoral antibodies against certain glomerular antigens (nephrotoxic antibodies) may reside in IgM (18) The association is probably also patho-genetically noteworthy in this respect In fact the histologic pictures of nephrotoxic serum nephritis and AP nephropathy possess a cer tain mutual resemblance (6 19) As far as we know however no clear cut proof has been presented for the existence of antiglomerular antibodies in AP On the other hand infec tion precedes AP in most cases (77% in this series) and may also have occurred in the re maining patients in a latent form Micro-orga nisms may differ in respect of the antibody response they cause certain microbes especi ally those with polysaccharide surface anti gens stimulating antibody response of the IgM type As giant molecules IgM antigen complexes would most probably be tagged in the glomerular capillaries causing damage there by complement activation

Could it be that AP with nephropathy may arise in patients who have experienced an in fection with pronounced antibody response of the IgM type? All 5 patients with elevated IgM and nephropathy in the present series had had preceding infections

Whatever the cause and pathogenic signifi cance of the elevated IgM levels in AP we emphasize that it may serve as an outstanding sign of more severe disease and a prediction of a poorer outcome

$p<0\ 0125$ as compared with group A

RESULTS

The concentrations of IgG IgA IgM IgD and IgE in the total series are shown in Table 1

The level of IgG was similar to that in healthy Finnish children of the same ages (7) and no significant differences were noted in the serum IgG levels of the four AP subgroups

The concentration of IgA was significantly elevated ($p<0\ 001$) in the patients with recent AP and remained at the same level in those with recurrent purpura melena or haematuria At 3–16 (mean 8) days after the healing of an uncomplicated anaphylactoid purpura the serum IgA was still at the same high level

The level of IgM in patients with recent AP was elevated significantly ($p<0\ 001$) as compared with that of healthy Finnish children of the same ages (7) while the concentration of 2 81±1 36 g/l found in patients with AP nephropathy was significantly higher than that in the patients with recent uncomplicated AP ($p<0\ 0125$) However the serum IgM levels of patients with AP nephropathy in the initial stage of recent AP (1 22±0 83 g/l) were not higher than those in the patients with recent AP as a whole In 3 patients with elevated IgM at the initial stage of nephropathy the level of IgM was normal when measured 1–3 years later

IgD was present in the serum of 11 out of the 18 patients studied in this respect The serum levels of IgE and IgD showed no significant difference as compared with those reported in healthy Swedish children (3) nor were any differences found between the AP subgroups

DISCUSSION

Previous studies have demonstrated that the serum IgA concentration is elevated in AP (8 15 16) and it seems evident from the pres

PITUITARY THYROID RESPONSIVENESS TO THYROTROPIN RELEASING HORMONE IN PRETERM AND SMALL FOR GESTATIONAL AGE NEWBORNS

B BROCK JACOBSEN H ANDERSEN H DIGE PETERSEN and L HUMMER

Fr m the Universit Cl nic of Paediatrics Children s Hospital Fuglebakken and the Department of Nuclear Medicine Rigshospitalet Copenhagen Denmark

ABSTRACT Jacobsen B B Andersen H Dige Petersen H and Hummer L (University Clinic of Paediatrics Children s Hospital Fuglebakken and Department of Nuclear Medicine Rigshospitalet Copenhagen Denmark) Pituitary thyroid responsiveness to thyrotropin releasing hormone in preterm and small for gestational age newborns Acta Paediatr Scand 66 541 1977 —A dose of 40 μg TRH was injected intravenously in 12 preterm (PT) and 15 small for gestational age (SGA) babies (with advanced gestational ages) between 5 and 167 hours after birth Serum thyrotropin (TSH) was measured prior to and 30 and 180 min after TRH serum thyroxine (T) and serum triiodothyronine (T) were measured prior to and 180 min after TRH The percentage increase in serum TSH in PT and SGA babies was comparable to that of fullterm newborns The serum TSH 30 min after TRH in SGA newborns was significantly correlated to basal TSH values such a correlation could not be shown in the preterms One SGA and four PT babies had a repeat TRH test performed later in infancy In all but one PT with a gestational age of 27 weeks the TSH rise was lower than in the neonatal period The thyroid hormone responses after TRH were similar in the two groups of babies The percentage increase above basal levels were Median serum T_3 increase about 46% and median serum T_4 increase about 14% It is concluded that in low birth weight newborn babies the pituitary TSH response to exogenous TRH was like that detected in fullterm newborns and more pronounced than later in infancy The effect of endogenous TSH as measured by thyroid hormone increases was of the same magnitude as observed in fullterms and in adults

KEY WORDS Thyrotropin thyrotropin releasing hormone thyroid hormones preterm small for gestational age newborns

The anatomical and functional maturation of the hypothalamus and pituitary gland is supposed to occur at mid gestation At this time fetal serum concentrations of thyrotropin (TSH) and other pituitary hormones increase (13 17 18 19) Thyrotropin releasing hormone (TRH) seems however to be present in fetal brain even earlier (33)

After birth a pronounced but transitory increase in serum levels of TSH and thyroid hormones appears in fullterm (1 6 9 11 12 21 29) and low birth weight babies (23 25) Lemarchand Béraud et al (25) observed a more marked and sustained TSH rise in low birth weight neonates than in fullterm newborns but we found a TSH response to birth which did not diffe in the two groups although the TSH concentration in cord blood was higher in preterm and small for gestational age babies (23 24) the thyroid hormone levels in blood were different in fullterm preterm and small for gestational age newborns the lowest values observed in preterm babies (23)

The mechanisms underlying these changes in serum concentrations of TSH and thyroid

PITUITARY THYROID RESPONSIVENESS TO THYROTROPIN RELEASING HORMONE IN PRETERM AND SMALL FOR GESTATIONAL AGE NEWBORNS

B BROCK JACOBSEN H ANDERSEN H DIGE PETERSEN and L HUMMER

From the University Clinic of Paediatrics Children s Hospital Fuglebakken and the Department of Nuclear Medicine Rigshospitalet Copenhagen Denmark

ABSTRACT Jacobsen B B Andersen H Dige Petersen H and Hummer L (University Clinic of Paediatrics Children s Hospital Fuglebakken and Department of Nuclear Medicine Rigshospitalet Copenhagen Denmark) Pituitary thyroid responsiveness to thyrotropin releasing hormone in preterm and small for gestational age newborns Acta Paediatr Scand 66 541 1977 —A dose of 40 μg TRH was injected intravenously in 12 preterm (PT) and 15 small for gestational age (SGA) babies (with advanced gestational ages) between 5 and 167 hours after birth Serum thyrotropin (TSH) was measured prior to and 30 and 180 min after TRH serum thyroxine (T) and serum triiodothyronine (T_3) were measured prior to and 180 min after TRH The percentage increase in serum TSH in PT and SGA babies was comparable to that of fullterm newborns The serum TSH 30 min after TRH in SGA newborns was significantly correlated to basal TSH values such a correlation could not be shown in the preterms One SGA and four PT babies had a repeat TRH test performed later in infancy In all but one PT with a gestational age of 27 weeks the TSH rise was lower than in the neonatal period The thyroid hormone responses after TRH were similar in the two groups of babies The percentage increase above basal levels were Median serum T_3 increase about 46% and median serum T increase about 14% It is concluded that in low birth weight newborn babies the pituitary TSH response to exogenous TRH was like that detected in fullterm newborns and more pronounced than later in infancy The effect of endogenous TSH as measured by thyroid hormone increases was of the same magnitude as observed in fullterms and in adults

KEY WORDS Thyrotropin thyrotropin releasing hormone thyroid hormones preterm small for gestational age newborns

The anatomical and functional maturation of the hypothalamus and pituitary gland is supposed to occur at mid gestation At this time fetal serum concentrations of thyrotropin (TSH) and other pituitary hormones increase (13 17 18 19) Thyrotropin releasing hormone (TRH) seems however to be present in fetal brain even earlier (33)

After birth a pronounced but transitory increase in serum levels of TSH and thyroid hormones appears in fullterm (1 6 9 11 12 21 29) and low birth weight babies (23 25) Lemarchand Béraud et al (25) observed a more marked and sustained TSH rise in low birth weight neonates than in fullterm newborns but we found a TSH response to birth which did not diffe in the two groups although the TSH concentration in cord blood was higher in preterm and small for gestational age babies (23 24) the thyroid hormone levels in blood were different in fullterm preterm and small for gestational age newborns the lowest values observed in preterm babies (23)

The mechanisms underlying these changes in serum concentrations of TSH and thyroid

hormones are not clear (11 12) An increased endogenous TRH secretion during the first postnatal days has been suggested in fullterms (12 22)

In order to evaluate the pituitary and thyroid gland responsiveness in preterm and small for gestational age babies during the early neonatal period measurements of serum TSH and thyroid hormone concentrations were performed after exogenous TRH stimulation

MATERIALS AND METHODS

Studies were carried out in 27 euthyroid newborn low birth weight infants between 5 and 167 hours after birth (Tables 1 and 2) The parents were informed and consent obtained Twelve preterm (PT) babies of 27 to 36 weeks gestation and with weights appropriate for dates and 15 small for gestational age (SGA) babies were included in the study (Tables 1 and 2) All SGA babies—except patient no 26—were born at term (gestational age 37 to 40 weeks) Gestational age was assessed according to Bjerkedal et al (2) Infants with birth weight below the 10th percentile and with typical clinical signs were defined as SGA babies (11) Two of the SGA babies—nos 14 and 23—were perinatally asphyxiated with apgar scores 0/1 min 1/2 min 3/3 min and 4/1 min 6/5 min 9/10 min respectively but were in a good clinical state when tested Many of the infants were placed in incubators all had normal body temperature when studied The body weight in PT babies ranged from 1 155 to 2 350 g and in SGA babies from 1 370 to 2 630 g The body weights in the two groups did not differ statistically ($p>0$ 1) If the SGA infants nos 13 14 and 15 were excluded the distribution of post natal ages was approximately equal in both groups

In order to eliminate any possible influence of a circadian rhythm of TSH (31) all studies were started in the morning between 8 30 and 9 00 a m Synthetic TRH —pyroglutamyl histidyl proline amide (Hoechst AG)—40 μg was administered intravenously Blood was centrifuged immediately and serum stored at −20°C until analysed No side effects were seen The patients were included in a later prospective study So far 5 patients have been restudied (Table 3)

Serum concentrations of TSH were measured prior to and 30 min and 180 min after TRH injection In a preliminary study no significant increase in thyroid hormone concentration was observed during the first 30 min after TRH for which reason only basal values and serum concentrations 180 min after TRH were determined

Serum TSH was measured by double antibody RIA technique (8) The results are expressed in terms of mU of research Standard A The detection limit of the assay is calculated to be 0 2 mU/l serum The intra assay coefficient of variation is 6% at levels from 2 5 to 25 mU/l and 12% at levels lower than 2 5 mU/l and higher than 25 mU/l The inter assay coefficient of variation is 16% at levels from 2 5 to 10 mU/l 6% from 10 to 25 mU/l and 25% at levels lower than 2 5 mU/l and higher than 25 mU/l based on a weekly set up during one year

Serum thyroxine (T_4) was measured using a modification of the competitive binding technique (Tetralute Ames) reported by Braverman et al (3) The detection limit of the assay is 25 nmol/l The intra assay coefficient of variation is 4% in the range 77–129 nmol/l and 6–10% outside this range The inter assay coefficient of variation is 9% at levels higher than 129 nmol/l 6% at levels between 77 and 129 nmol/l and 11% for values below 77 nmol/l

Serum triiodothyronine (T_3) was measured radioimmunologically as described by Gharib et al (16) The detection limit is 0 10 nmol/l and the intra assay and inter assay coefficient of variation is 5% in the range 1 10 to 2 40 nmol/l and 8% at levels lower and higher than these values Normal range of serum TSH T_4 and T_3 for newborns of various maturity during the first 6 days of life has been reported elsewhere (23) All analyses were performed in duplicate

Calculations of median and Spearman s coefficient of rank correlation (*R*) followed standard statistical methods (7) Further the Wilcoxon test for two samples and the Wilcoxon test for pair differences were employed (7) In the calculations values below the sensitivity limit of the TSH assay are expressed as 0 1 mU/l

RESULTS

Basal values of serum TSH and thyroid hormones

The basal values of *serum TSH* seemed to be higher in SGA than in PT babies (Tables 1 and 2) and the difference could probably not be ascribed to differences in post natal age After 72 or 96 hours all basal values were within the normal range of adults The basal *thyroid hormone* concentrations in serum tended to be higher in SGA than in PT babies but did not differ statistically ($p>0$ 1) The higher basal values of serum T_4 correlated significantly with the higher serum T_3 levels in PT ($r=0$ 73 $p<0$ 05) and in SGA ($r=0$ 70 $p<0$ 05) babies Obviously there was no relationship between basal values of serum TSH and thyroid hormones

Serum TSH 30 min after TRH injection

After administration of TRH a significant rise in serum TSH concentration occurred in all

Table 1 *Clinical data and effect of 40 μg of i v TRH on serum concentrations of TSH and thyroid hormones in preterm newborn babies*

Serum TSH time 0 30 and 180 min after TRH injection
Serum T and $-T_3$ time 0 and 180 min after TRH injection

subjects (Tables 1 and 2) The median increase in serum TSH was 7 times in PT and 4–5 times in SGA babies (Fig 1) and the 30 min TSH values in PT and SGA babies did not differ statistically ($p>0$ 05) In SGA newborns the higher 30 min values of TSH correlated with the higher basal TSH values ($r=0$ 67 $p<0$ 02) whereas in PT babies—who had lower basal values—the correlation was not significant ($r=0$ 51 $p>0$ 05) In the asphyxiated babies a normal TSH response appeared

The dose of TRH per kg body weight ranged from 15 2 to 34 6 μg but the TSH increase was not correlated to the TRH dose The serum TSH increase *within* the maturity groups was not correlated to head circumfer

hormones are not clear (11, 12). An increased endogenous TRH secretion during the first postnatal days has been suggested in fullterms (12, 22).

In order to evaluate the pituitary and thyroid gland responsiveness in preterm and small for gestational age babies during the early neonatal period, measurements of serum TSH and thyroid hormone concentrations were performed after exogenous TRH stimulation.

MATERIALS AND METHODS

Studies were carried out in 27 euthyroid newborn low birth weight infants between 5 and 167 hours after birth (Tables 1 and 2). The parents were informed and consent obtained. Twelve preterm (PT) babies of 27 to 36 weeks gestation and with weights appropriate for dates and 15 small for gestational age (SGA) babies were included in the study (Tables 1 and 2). All SGA babies—except patient no. 26—were born at term (gestational age 37 to 40 weeks). Gestational age was assessed according to Bjerkedal et al. (2). Infants with birth weight below the 10th percentile and with typical clinical signs were defined as SGA babies (11). Two of the SGA babies—nos. 14 and 23—were perinatally asphyxiated with apgar scores 0/1 min, 1/2 min, 3/3 min and 4/1 min, 6/5 min, 9/10 min, respectively, but were in a good clinical state when tested. Many of the infants were placed in incubators, all had normal body temperature when studied. The body weight in PT babies ranged from 1 155 to 2 350 g and in SGA babies from 1 370 to 2 630 g. The body weights in the two groups did not differ statistically ($p>0.1$). If the SGA infants nos. 13, 14 and 15 were excluded, the distribution of post natal ages was approximately equal in both groups.

In order to eliminate any possible influence of a circadian rhythm of TSH (31), all studies were started in the morning between 8.30 and 9.00 a.m. Synthetic TRH—pyroglutamyl histidyl proline amide (Hoechst AG)—40 µg was administered intravenously. Blood was centrifuged immediately and serum stored at −20°C until analysed. No side effects were seen. The patients were included in a later prospective study. So far 5 patients have been restudied (Table 3).

Serum concentrations of TSH were measured prior to and 30 min and 180 min after TRH injection. In a preliminary study no significant increase in thyroid hormone concentration was observed during the first 30 min after TRH, for which reason only basal values and serum concentrations 180 min after TRH were determined.

Serum TSH was measured by double antibody RIA technique (8). The results are expressed in terms of mU of research Standard A. The detection limit of the assay is calculated to be 0.2 mU/l serum. The intra assay coefficient of variation is 6% at levels from 2.5 to 25 mU/l and 12% at levels lower than 2.5 mU/l and higher than 25 mU/l. The inter assay coefficient of variation is 16% at levels from 2.5 to 10 mU/l, 6% from 10 to 25 mU/l and 25% at levels lower than 2.5 mU/l and higher than 25 mU/l based on a weekly set up during one year.

Serum thyroxine (T_4) was measured using a modification of the competitive binding technique (Tetralute Ames) reported by Braverman et al. (3). The detection limit of the assay is 25 nmol/l. The intra assay coefficient of variation is 4% in the range 77–129 nmol/l and 6–10% outside this range. The inter assay coefficient of variation is 9% at levels higher than 129 nmol/l, 6% at levels between 77 and 129 nmol/l and 11% for values below 77 nmol/l.

Serum triiodothyronine (T_3) was measured radioimmunologically as described by Gharib et al. (16). The detection limit is 0.10 nmol/l and the intra assay and inter assay coefficient of variation is 5% in the range 1.10 to 2.40 nmol/l and 8% at levels lower and higher than these values. Normal range of serum TSH, T_4 and T_3 for newborns of various maturity during the first 6 days of life has been reported elsewhere (23). All analyses were performed in duplicate.

Calculations of median and Spearman's coefficient of rank correlation (R) followed standard statistical methods (7). Further, the Wilcoxon test for two samples and the Wilcoxon test for pair differences were employed (7). In the calculations, values below the sensitivity limit of the TSH assay are expressed as 0.1 mU/l.

RESULTS

Basal values of serum TSH and thyroid hormones

The basal values of *serum TSH* seemed to be higher in SGA than in PT babies (Tables 1 and 2), and the difference could probably not be ascribed to differences in post natal age. After 72 or 96 hours all basal values were within the normal range of adults. The basal *thyroid hormone* concentrations in serum tended to be higher in SGA than in PT babies but did not differ statistically ($p>0.1$). The higher basal values of serum T_4 correlated significantly with the higher serum T_3 levels in PT ($r=0.73$, $p<0.05$) and in SGA ($r=0.70$, $p<0.05$) babies. Obviously, there was no relationship between basal values of serum TSH and thyroid hormones.

Serum TSH 30 min after TRH injection

After administration of TRH a significant rise in serum TSH concentration occurred in all

able 1 *Clinical data and effect of 40 μg of i v TRH on serum concentrations of TSH and yroid hormones in preterm newborn babies*

Serum TSH time 0 30 and 180 min after TRH injection
Serum T_4 and $-T_3$ time 0 and 180 min after TRH injection

subjects (Tables 1 and 2) The median increase in serum TSH was 7 times in PT and 4–5 times in SGA babies (Fig 1) and the 30 *min TSH* values in PT and SGA babies did not differ statistically ($p>0\ 05$) In SGA newborns the higher 30 min values of TSH correlated with the higher basal TSH values ($r=0\ 67$ $p<0\ 02$) whereas in PT babies—who had lower basal values—the correlation was not significant ($r=0\ 51$ $p>0\ 05$) In the asphyxiated babies a nor *mal TSH* response appeared

The dose of TRH per kg body weight ranged from 15 2 to 34 6 μg but the TSH increase was not correlated to the TRH dose The serum TSH increase *within* the maturity groups was not correlated to head circumfer

hormones are not clear (11, 12) An increased endogenous TRH secretion during the first postnatal days has been suggested in fullterms (12 22)

In order to evaluate the pituitary and thyroid gland responsiveness in preterm and small for gestational age babies during the early neonatal period measurements of serum TSH and thyroid hormone concentrations were performed after exogenous TRH stimulation

MATERIALS AND METHODS

Studies were carried out in 27 euthyroid newborn low birth weight infants between 5 and 167 hours after birth (Tables 1 and 2) The parents were informed and consent obtained Twelve preterm (PT) babies of 27 to 36 weeks gestation and with weights appropriate for dates and 15 small for gestational age (SGA) babies were included in the study (Tables 1 and 2) All SGA babies—except patient no 26—were born at term (gestational age 37 to 40 weeks) Gestational age was assessed according to Bjerkedal et al (2) Infants with birth weight below the 10th percentile and with typical clinical signs were defined as SGA babies (11) Two of the SGA babies—nos 14 and 23—were perinatally asphyxiated with apgar scores 0/1 min 1/2 min 3/3 min and 4/1 min 6/5 min 9/10 min respectively but were in a good clinical state when tested Many of the infants were placed in incubators all had normal body temperature when studied The body weight in PT babies ranged from 1 155 to 2 350 g and in SGA babies from 1 370 to 2 630 g The body weights in the two groups did not differ statistically ($p>0.1$) If the SGA infants nos 13 14 and 15 were excluded the distribution of post natal ages was approximately equal in both groups

In order to eliminate any possible influence of a circadian rhythm of TSH (31) all studies were started in the morning between 8 30 and 9 00 a m Synthetic TRH —pyroglutamyl histidyl proline amide (Hoechst AG)—40 μg was administered intravenously Blood was centrifuged immediately and serum stored at −20°C until analysed No side effects were seen The patients were included in a later prospective study So far 5 patients have been restudied (Table 3)

Serum concentrations of TSH were measured prior to and 30 min and 180 min after TRH injection In a preliminary study no significant increase in thyroid hormone concentration was observed during the first 30 min after TRH for which reason only basal values and serum concentrations 180 min after TRH were determined

Serum TSH was measured by double antibody RIA technique (8) The results are expressed in terms of mU of research Standard A The detection limit of the assay is calculated to be 0 2 mU/l serum The intra assay coefficient of variation is 6% at levels from 2 5 to 25 mU/l and 12% at levels lower than 2 5 mU/l and higher than 25 mU/l The inter assay coefficient of variation is 16% at levels from 2 5 to 10 mU/l 6% from 10 to 25 mU/l and 25% at levels lower than 2 5 mU/l and higher than 25 mU/l based on a weekly set up during one year

Serum thyroxine (T_4) was measured using a modification of the competitive binding technique (Tetralute Ames) reported by Braverman et al (3) The detection limit of the assay is 25 nmol/l The intra assay coefficient of variation is 4% in the range 77–129 nmol/l and 6–10% outside this range The inter assay coefficient of variation is 9% at levels higher than 129 nmol/l 6% at levels between 77 and 129 nmol/l and 11% for values below 77 nmol/l

Serum triiodothyronine (T_3) was measured radioimmunologically as described by Gharib et al (16) The detection limit is 0 10 nmol/l and the intra assay and inter assay coefficient of variation is 5% in the range 1 10 to 2 40 nmol/l and 8% at levels lower and higher than these values Normal range of serum TSH T_4 and T_3 for newborns of various maturity during the first 6 days of life has been reported elsewhere (23) All analyses were performed in duplicate

Calculations of median and Spearman s coefficient of rank correlation (R) followed standard statistical methods (7) Further the Wilcoxon test for two samples and the Wilcoxon test for pair differences were employed (7) In the calculations values below the sensitivity limit of the TSH assay are expressed as 0 1 mU/l

Serum TSH time 0 30 and 180 min after TRH injection
[b] Serum T_4 and $-T_3$ time 0 and 180 min after TRH injection

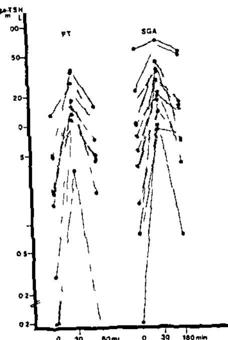

Fig 1 Serum concentration of TSH prior to and 30 and 180 min after injection of TSH 40 μg i v in preterm (PT) and small for gestational age (SGA) newborn babies (The ordinate is log serum TSH concentration)

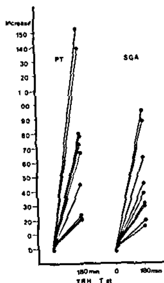

Fig 2 The increases in serum triiodothyronine (T_3) concentrations 180 min after injection of TRH 40 μg i v in preterm (PT) and small for gestational age (SGA) newborn babies (The increase is the percentage increase above basal level)

ence gestational age or basal thyroid hormone concentration

Serum TSH and thyroid hormone values 180 min after TRH injection

In most PT and SGA babies the serum concentration of TSH remained above basal level 180 min after TRH administration (PT $p<0.01$ and SGA $p<0.05$) (Fig 1)

A significant rise in serum concentrations of thyroid hormones was noted in both groups of newborns 180 min after TRH injection (Tables 1 and 2) The serum T_3 increase was invariably present and was more pronounced than the serum T_4 increase (Fig 2) A wide range of T_4 and T_3 increases was seen the median T_3 increase was about 46% in both groups and the median T_4 increase was about 14% (Fig 3) in two infants no T_4 increase could be shown No significant correlation was found between the increase in thyroid hormones and TSH response age or body weight

There was no significant difference between PT and SGA neonates ($p>0.1$)

A second TRH test later in infancy

In four PT and one SGA infants (Table 3) a second TRH test was performed 7 to 103 days after the first test It is seen that in all infants—except patient no 12 with a birth weight of 1210 g—the *TSH response* was

[b] Serum T_4 and $-T_3$ time 0 and 180 min after TRH injection

ferences in responsiveness to TRH but also the actual TSH secretion rate at the time of study and accordingly the statistical analyses of pooled data may be subject to criticism

The TRH dose per kg body weight in the present as well as in the previous study (22) was high as compared with the doses usually given to adults (8 20 32) We found no correlation between the TRH dose per kg and the TSH response probably a maximal stimulation of the pituitary gland was obtained in both studies The serum TSH values 30 min after TRH correlated with basal TSH values in SGA babies like in fullterm newborns (22) and in euthyroid adults (32) but the responses seemed more variable in PT neonates The 30 min TSH value which is supposed to be a maximum TSH level after exogenous TRH (22) was higher during the neonatal period than later in infancy—except for the above mentioned premature infant

These findings indicate that also in low birth weight newborns—preterm babies as well as infants with advanced gestational age —the pituitary responsiveness to TRH is normal The results of this study confirm and extend previous studies (13 15 18 19 24 28) on the evolution of the pituitary-thyroid system in the fetus As low birth weight neonates are responsive to TRH this substance may be hypothesized as the initiater of the postnatal TSH hypersecretion not only in mature (23) but also in premature neonates

The increase in serum concentrations of thyroid hormones during the TRH test was probably induced by endogenous TSH The more pronounced relative increase occurred in serum T_3 concentrations a less consistent increase was observed in serum T_4 values The higher relative T_3 than T_4 responses also agree with the finding in fullterm babies that the serum T_3 increase following delivery is more pronounced than the serum T_4 rise (1 6 9 23 29) The thyroid hormone responses during serum TRH tests were although variable *not* quantitatively or qualitatively different from the responses seen in 12 fullterm newborns (unpublished results)—and not different from that seen in euthyroid adults after TRH (4 24) This is in agreement with biochemical studies of T_4/T_3 ratios in the thyroid glands in which the magnitude of the ratios were found to be the same in fetal and adult glands (14)

more pronounced immediately after birth The basal serum T_3 level was considerable higher at the second test in 3 of 4 patients but the relative *thyroid hormone responses* seemed to be of the same magnitude in the two tests *The TRH dose per kg body weight* ranged from 11 3 to 19 9 µg Statistical analysis was omitted because of the small number of subjects

DISCUSSION

Infants with low birth weight frequently differ from fullterm mature babies as to the pattern of postnatal growth (5 26 27 30) and for this reason *pituitary thyroid disorders* may be suspected We have elsewhere reported that a TSH hypersecretion appears in fullterm as well as in preterm and small for gestational age babies during the early neonatal period (23) The serum TSH values in the three maturity groups did not differ significantly in contrast to the thyroid hormone levels which were lower in the low birth weight babies (23) A TRH stimulation test performed in fullterm mature newborn babies demonstrated a percentage increase in serum TSH as seen in euthyroid adults in spite of high basal levels of TSH and T_4 (22) This was hypothetically interpreted as a change at the pituitary thyrotroph cell level caused by endogenous TRH secretion *in the fullterm* newborn baby

Results of TRH stimulation have however not been reported in low birth weight newborns Previous suggestions that maturation of the hypothalamic–pituitary–thyroid system is *completed at 11–24 weeks gestation* were based upon histological studies of fetal pituitary glands and on measurements of hormone concentrations in fetal blood (13 15 17 18 19 24) The present study showed that the TSH response to exogenous TRH in PT babies was of the same magnitude as observed in SGA babies and within the range of full terms (23) All children studied did respond to TRH the lowest TSH response was seen at 27 weeks gestation (no 12) The comparison of TSH responses between the groups is impeded by the non steady state of serum TSH secretion *during the first postnatal days* For this reason differences in the maximum serum TSH values after TRH not only reflect dif

CELLULAR AND HUMORAL FACTORS INVOLVEMENT IN THE ENHANCED NBT REDUCTION BY NEUTROPHIL LEUCOCYTES OF NEWBORN INFANTS

P A TOVO and A PONZONE

From the Department of Paediatrics University of Turin and the Regina Margherita Children s Hospital Turin Italy

ABSTRACT Tovo P A and Ponzone A (Department of Paediatrics University of Turin and Regina Margherita Children s Hospital Turin Italy) Cellular and humoral factors involvement in the enhanced NBT reduction by neutrophil leucocytes of newborn infants Acta Paediatr Scand 66 549 1977.—The histochemical NBT test was performed on blood samples from ten healthy newborn infants High spontaneous NBT reduction has been confirmed for neutrophils and assessed for monocytes The stimulation of both neutrophils and monocytes with *Escherichia coli* endotoxin induces a statistically significant increase of NBT positive cells The reason for the false positi e test results in neonates was investigated by incubating neutrophils from adult donors and for different time periods in either neonatal or adult plasma before the addition of NBT NBT reduction by adult neutrophils was increased after incubation in neonatal plasma and this increase was related to the concentration of the plasma used Maximum NBT reduction was observed after 90 min of incubation at which time the NBT scores of adult cells incubated in neonatal plasma were similar to the results of tests performed on whole neonatal blood It is concluded that neonatal leucocytes demonstrate efficient spontaneous and stimulated phagocytosis and that there are in the plasma of neonates humoral factors which stimulate phagocytosis by neutrophils and are thus responsible for the false positive NBT test results observed in these subjects

KEY WORDS NBT test phagocytosis neonatal neutrophils

The nitroblue tetrazolium (NBT) test initially introduced as a rapid aid to the differential diagnosis of a pyogenic infection did not fulfill its early promise (2 7 11 14) With this test surprisingly high false positive NBT test results were demonstrated in neonates (1 3 4 7 10) The purpose of this study was to verify that NBT reduction is enhanced in neonates and to determine whether cellular or humoral factors are responsible for the enhanced dye reduction

MATERIALS AND METHODS

NBT tests

The study group consisted of 10 clinically and haematologically healthy at term infants from 8 hours to 5 days old The histochemical NBT reduction test (normal test) of Park et al (8) was modified by incubating 0 5 ml of venous blood taken into heparin (50 u/ml) with an equal amount of 0 2% NBT (Sigma) solution and phosphate buffered saline 0 15 M solution pH 7 2 in a siliconised syringe at 37°C for 15 min and then at room temperature for 10 min

For the stimulated NBT test (9) 5 µg of *Escherichia coli* endotoxin (type 055 B5 Difco) in 0 05 ml of 0 15 M phosphate buffered saline was mixed with 0 5 ml of blood in a siliconised syringe and incubated at 37 C for 10 min before the addition of the NBT whereupon subsequent steps were the same as for the normal test Thin smears were made on glass slides air-dried and stained with May-Grunwald-Giemsa s stain At least 00 cells for each subject were counted Only those cells containing a definite formazan deposit were classified as positive All counts were performed independently by two individuals and mean values for each group of experiments were calculated

CELLULAR AND HUMORAL FACTORS INVOLVEMENT IN THE ENHANCED NBT REDUCTION BY NEUTROPHIL LEUCOCYTES OF NEWBORN INFANTS

P A TOVO and A PONZONE

From the Department of Paediatrics University of Turin and the Regina Margherita Children s Hospital Turin Italy

ABSTRACT Tovo P A and Ponzone A (Department of Paediatrics University of Turin and Regina Margherita Children s Hospital Turin Italy) Cellular and humoral factors involvement in the enhanced NBT reduction by neutrophil leucocytes of newborn infants Acta Paediatr Scand 66 549 1977.—The histochemical NBT test was performed on blood samples from ten healthy newborn infants High spontaneous NBT reduction has been confirmed for neutrophils and assessed for monocytes The stimulation of both neutrophils and monocytes with *Escherichia coli* endotoxin induces a statistically significant increase of NBT positive cells The reason for the false positive test results in neonates was investigated by incubating neutrophils from adult donors and for different time periods in either neonatal or adult plasma before the addition of NBT NBT reduction by adult neutrophils was increased after incubation in neonatal plasma and this increase was related to the concentration of the plasma used Maximum NBT reduction was observed after 90 min of incubation at which time the NBT scores of adult cells incubated in neonatal plasma were similar to the results of tests performed on whole neonatal blood It is concluded that neonatal leucocytes demonstrate efficient spontaneous and stimulated phagocytosis and that there are in the plasma of neonates humoral factors which stimulate phagocytosis by neutrophils and are thus responsible for the fal e positive NBT test results observed in these subjects

KEY WORDS NBT test phagocytosis neonatal neutrophils

The nitroblue tetrazolium (NBT) test initially introduced as a rapid aid to the differential diagnosis of a pyogenic infection did not fulfill its early promise (2 7 11 14) With this test surprisingly high false positive NBT test results were demonstrated in neonates (1 3 4 7 10) The purpose of this study was to verify that NBT reduction is enhanced in neonates and to determine whether cellular or humoral factors are responsible for the enhanced dye reduction

MATERIALS AND METHODS

NBT tests

The study group consisted of 10 clinically and haematologically healthy at term infants from 8 hours to 5 days old The histochemical NBT reduction test (normal test) of Park et al (8) was modified by incubating 0 5 ml of venous blood taken into heparin (50 u/ml) with an equal amount of 0 2% NBT (Sigma) solution and phosphate buffered saline 0 15 M solution pH 7 2 in a siliconised syringe at 37°C for 15 min and then at room temperature for 10 min

For the stimulated NBT test (9) 5 μg of *Escherichia coli* endotoxin (type 055 B5 Difco) in 0 05 ml of 0 15 M phosphate buffered saline was mixed with 0 5 ml of blood in a siliconised syringe and incubated at 37°C for 10 min before the addition of the NBT whereupon subsequent steps were the same as for the normal test Thin smears were made on glass slides air-dried and stained with May-Grunwald-Giemsa s stain At least 00 cells for each subject were counted Only those cells containing a definite formazan deposit were classified as positive All counts were performed independently by two individuals and mean values for each group of experiments were calculated

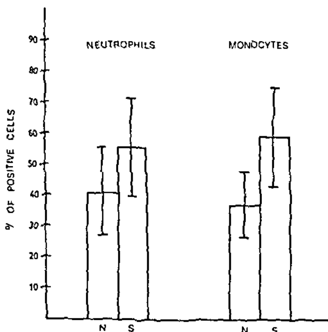

Fig 1 NBT reduction by neutrophils and monocytes of newborn infants in the normal (*N*) and stimulated (*S*) tests The mean and standard deviation of 10 tests in each group are shown

Effect of neonatal plasma on reduction of NBT by adult neutrophils

Plasma was obtained from blood from 5 neonates (umbellical cord blood) and from 5 healthy adults anticoagulated with heparin (50 u/ml) Neutrophil leucocytes were obtained from 5 healthy adults ABO blood group O negative Blood (30 ml) taken into heparin (50 u/ml) was allowed to sediment at room temperature for 2 hours The leucocyte rich supernatant was removed and centrifuged at 110 g for 10 min The leucocyte pellet was resuspended and washed twice with TC 199 medium (Difco) and adjusted to a final concentration of 20 000 neutrophils/mm³ An aliquot (1 0 ml) of this suspension was incubated with an equal volume of adult and neonatal plasma each diluted to 5% and 20% in TC 199 at 37°C Aliquots (0 2 ml) were removed after 15 30 45 60 and 90 min of incubation and NBT reduction tested with a normal NBT test

RESULTS

Results of normal and stimulated NBT test are given in Fig 1 In both the normal and the stimulated tests NBT reduction by monocytes was similar to that of neutrophil polymorphs and both were much greater than is observed in normal adults (9 11 16)

The effect of incubation of adult neutrophils in heterologous and neonatal plasma is shown in Table 1 Normal adult neutrophils incubated in heterologous adult plasma showed NBT positive scores similar to those obtained with the NBT test performed directly on adult peripheral blood When the cells were incubated in neonatal plasma NBT reduction was increased and was greater with the higher concentration of plasma After 90 min of incubation the NBT scores of adult cells were similar to the abnormally higher results obtained with neonatal blood The effect of adult plasma on the reduction of NBT by neutrophils from newborn infants was repeatedly unsuccessful because of the extreme fragility of neonatal cells which resulted in cell damage and subsequent unreliability in performing differential counts

DISCUSSION

This study confirmed that neutrophils of neonates give abnormally high results in the NBT test In addition it was shown that still more neutrophils could be induced to reduce the dye by stimulation with endotoxin This indicates that the neonate s neutrophils have a high capacity to phagocytose and reduce NBT under a normal stimulus (NBT+heparin) and a strong stimulus (endotoxin+NBT+heparin) Hence it is likely that the newborn infant possesses efficient cellular mechanisms for phagocytosis and for killing of ingested microbes

The rate of spontaneous reduction of NBT is probably due to humoral factors as shown in the second series of experiments Incubation of neutrophils of healthy adults in neonatal plasma increased the proportion of the cells that reduced the dye

Other humoral factors are capable of stimulating phagocytosis and reduction of complexed NBT in vitro and/or in vivo The serum of subjects with acute infections may enhance NBT reduction by normal neutrophil leucocytes (13) Orosomucoid one of the acute phase proteins displays a similar effect as do bacterial products including endotoxin and

Table 1 *Effect of adult and neonatal plasma upon reduction of NBT by adult neutrophils*

Mean and standard deviation of five studies

Plasma concentration	% NBT positive adult neutrophils at various time intervals of incubation (min)

Adult plasma 2 5%	6 6±4 9	7 4±3 0	6 8±4 6	15 2± 4 8	10 4± 4 5
Neonatal plasma 2 5%	13 [illegible]±6 9	10 0±5 4	13 2±7 1	23 2±10 4	35 8±11 8
Adult plasma 10%	9 4±4 1	13 0±7 4	8 0±4 7	14 0± 6 8	12 4± 7 6
Neonatal plasma 10%	13 [illegible]±4 8	18 4±6 3	21 6±8 7	33 6± 8 0	47 0±15 5

streptolysin (12 13) MIF has been shown to increase oxygen consumption and hexose monophosphate pathway activity (6) and tuftsin a tetrapeptide of splenic origin should also be regarded as a phagocytosis promoting factor (15)

Additional humoral factors may be present in the neonate Alpha feto-protein e g a polypeptide synthesized by the yolk sac and the fetal liver enhances NBT reduction when added to a suspension of normal neutrophils at a final concentration even lower than those found in the neonate (13) The NBT score of neutrophils decreases in parallel with the fall in the neonatal period of the serum concentration of this protein (5) It has been suggested that this protein may act as a *non specific* opsonin in the period preceeding the acquisition of specific immunoglobulin (13)

It may be concluded that neonate s neutrophils have efficient mechanisms of phagocytosis and metabolic changes compatible with normal intracellular bacterial killing In addition there are unidentified humoral factor(s) in neonatal plasma which promote NBT reduction by adult cells These findings are of physiological relevance and may be important as an index of normal phagocytic cell function in neonates against which phagocyte disfunction in these patients can be compared

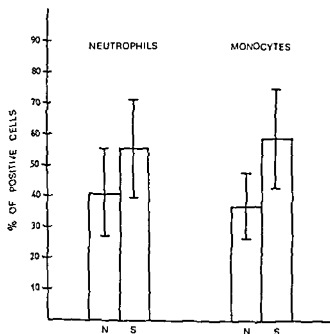

Fig 1 NBT reduction by neutrophils and monocytes of newborn infants in the normal (*N*) and stimulated (*S*) tests The mean and standard deviation of 10 tests in each group are shown

Effect of neonatal plasma on reduction of NBT by adult neutrophils

Plasma was obtained from blood from 5 neonates (umbellical cord blood) and from 5 healthy adults anticoagulated with heparin (50 u/ml) Neutrophil leucocytes were obtained from 5 healthy adults ABO blood group O negative Blood (30 ml) taken into heparin (50 u/ml) was allowed to sediment at room temperature for 2 hours The leucocyte rich supernatant was removed and centrifuged at 110 g for 10 min The leucocyte pellet was resuspended and washed twice with TC 199 medium (Difco) and adjusted to a final concentration of 20000 neutrophils/mm³ An aliquot (1 0 ml) of this suspension was incubated with an equal volume of adult and neonatal plasma each diluted to 5% and 20% in TC 199 at 37 C Aliquots (0 2 ml) were removed after 15 30 45 60 and 90 min of incubation and NBT reduction tested with a normal NBT test

RESULTS

Results of normal and stimulated NBT test are given in Fig 1 In both the normal and the stimulated tests NBT reduction by monocytes was similar to that of neutrophil polymorphs and both were much greater than is observed in normal adults (9 11 16)

The effect of incubation of adult neutrophils in heterologous and neonatal plasma is shown in Table I Normal adult neutrophils incubated in heterologous adult plasma showed NBT positive scores similar to those obtained with the NBT test performed directly on adult peripheral blood When the cells were incubated in neonatal plasma NBT reduction was increased and was greater with the higher concentration of plasma After 90 min of incubation the NBT scores of adult cells were similar to the abnormally higher results obtained with neonatal blood The effect of adult plasma on the reduction of NBT by neutrophils from newborn infants was repeatedly unsuccessful because of the extreme fragility of neonatal cells which resulted in cell damage and subsequent unreliability in performing differential counts

DISCUSSION

This study confirmed that neutrophils of neonates give abnormally high results in the NBT test In addition it was shown that still more neutrophils could be induced to reduce the dye by stimulation with endotoxin This indicates that the neonate s neutrophils have a high capacity to phagocytose and reduce NBT under a normal stimulus (NBT+heparin) and a strong stimulus (endotoxin+NBT+heparin) Hence it is likely that the newborn infant possesses efficient cellular mechanisms for phagocytosis and for killing of ingested microbes

The rate of spontaneous reduction of NBT is probably due to humoral factors as shown in the second series of experiments Incubation of neutrophils of healthy adults in neonatal plasma increased the proportion of the cells that reduced the dye

Other humoral factors are capable of stimulating phagocytosis and reduction of complexed NBT in vitro and/or in vivo The serum of subjects with acute infections may enhance NBT reduction by normal neutrophil leucocytes (13) Orosomucoid one of the acute phase proteins displays a similar effect as do bacterial products including endotoxin and

Table 1 *Effect of adult and neonatal plasma upon reduction of NBT by adult neutrophils*

Mean and standard deviation of five studies

Plasma concentration	% NBT positive adult neutrophils at various time intervals of incubation (min)				
	15	30	45	60	90
Adult plasma 7 5%	6 6±4 9	7 4±3 0	6 8±4 6	15 2± 4 8	10 4± 4 5
Neonatal plasma 2 5%	13 2±6 9	10 0±5 4	13 ?±7 1	23 2±10 4	35 8±11 8
Adult plasma 10%	9 4±4 1	13 0±7 4	8 0±4 7	14 0± 6 8	12 4± 7 6
Neonatal plasma 10%	13 2±4 8	18 4±6 3	21 6±8 7	33 6± 8 0	47 0±15 5

streptolysin (12 13) MIF has been shown to increase oxygen consumption and hexose monophosphate pathway activity (6) and tuftsin a tetrapeptide of splenic origin should also be regarded as a phagocytosis promoting factor (15)

Additional humoral factors may be present in the neonate Alpha feto protein e g a polypeptide synthesized by the yolk sac and the fetal liver enhances NBT reduction when added to a suspension of normal neutrophils at a final concentration even lower than those found in the neonate (13) The NBT score of neutrophils decreases in parallel with the fall in the neonatal period of the serum concentration of this protein (5) It has been suggested that this protein may act as a non specific opsonin in the period preceeding the acquisition of specific immunoglobulin (13)

It may be concluded that neonate s neutrophils have efficient mechanisms of phagocytosis and metabolic changes compatible with normal intracellular bacterial killing In addition there are unidentified humoral factor(s) in neonatal plasma which promote NBT reduction by adult cells These findings are of physiological relevance and may be important as an index of normal phagocytic cell function in neonates against which phagocyte disfunction in these patients can be compared

were performed When awake they were quiet and calm and showed little spontaneous motor activity The respiratory and heart rates were normal for the age

METHODS

The rate of evaporation from the skin was measured by a new method based on calculation of the vapour pressure gradient in the layer of air immediately adjacent to the skin surface (16 17 18) If this gradient is known the amount of water evaporated per unit time and area can be calculated from the equation

$$\frac{1}{A}\frac{dm}{dt} = -D\frac{\delta p}{\delta x} \qquad (1)$$

where

$\frac{1}{A}\frac{dm}{dt}$ is the amount of water evaporated per unit time and area (g/m h) in this paper expressed as evaporation rate (ER)

been determined by indirect methods, e.g. by measuring the flow and absolute humidity of the air supplied to and leaving the closed chamber in which the infant has been placed (10, 25) or by gravimetric techniques (5, 22, 23, 24). Using these methods it has been demonstrated that a relation exists between IWL and the relative humidity of the environment (10), that the water losses per surface unit are greater in infants with a low birth weight (5) and that a marked increase in the water losses takes place on exposure to radiant warmers (23).

When measuring water losses by placing the infant in a ventilated chamber it is necessary that the infant is in a good general condition and does not require nursing procedures during the period of measurement. This measuring system is slow and technical problems easily arise through the presence of urine and meconium in the measurement chamber, absorption of water in hygroscopic material, condensation in tubing etc.

Studies of water losses in very small low birth weight infants have therefore been carried out mostly by determination of the insensible weight loss (IL, g/h) with body weighing. Accurate results can only be obtained, however, when relatively long periods of measurement are used.

IWL consists partly of the total cutaneous water loss (CWL, g/h) and partly of water loss through the respiratory passages. According to Hey & Katz (10) CWL comprises about 75% of IWL. The cutaneous evaporative water loss is usually expressed per unit area and is then called transepidermal water loss (TEWL, g/m h). A selective study of TEWL in newborn infants and its relation to environmental factors, degree of activity and gestational age, for example, requires a method that allows:

- direct measurement of the rate of evaporation from the skin surface
- free evaporation from the skin surface
- quick measurements
- repeated measurements at short intervals
- measurements of relatively rapid changes
- measurement without discomfort to the infant

An instrument that satisfies the above criteria and which measures the rate of evaporation from small skin surfaces has therefore been developed for use in neonatal care and other fields.

In this paper the measurement technique employed will be briefly described. The purpose of the first study using this technique in neonatal care was to investigate the evaporation rate from the skin of newborn infants at varying degrees of ambient humidity and from different surface areas of the body. On the basis of the results obtained an easily handled way of estimating TEWL is proposed.

Abbreviations

ER	= the locally measured rate of evaporation from the surface of the skin (g/m²h)
IL	= insensible loss of weight (g/h)
IWL	= insensible loss of water (g/h)
CWL	= total cutaneous water loss (g/h)
TEWL	= transepidermal water loss (g/m²h)
Area	= area of a specified surface of the body (m²)
BSA	= total body surface area (m²)
H	= body height (m)
W	= body weight (kg)
$P_{H_2O\ amb}$	= ambient water vapour pressure (Pa)
RH_{amb}	= *ambient relative humidity (%)*
T_{amb}	= ambient temperature (°C)
T_{body}	= body temperature (°C)

SUBJECTS

Measurements of ER were performed on 8 healthy newborn infants born in the 38th–40th week of pregnancy. The measurements were performed during the first 30 hours after delivery. The infant's skin was not washed or wiped before the measurements. In 19 infants (Table 1) ER was measured at varying ambient humidities (RH_{amb}) and in 9 infants (Table 2) ER was measured from different skin surfaces under constant environmental conditions. The infants were often asleep when the measurements

were performed When awake they were quiet and calm and showed little spontaneous motor activity The respiratory and heart rates were normal for the age

METHODS

The rate of evaporation from the skin was measured by *a new method based on calculation of the vapour pressure* gradient in the layer of air immediately adjacent to the skin surface (16 17 18) If this gradient is known the amount of water evaporated per unit time and area can be calculated from the equation

$$\frac{1}{A}\frac{dm}{dt} = -D\frac{\delta p}{\delta x} \qquad (1)$$

where

$\frac{1}{A}\frac{dm}{dt}$ is the amount of water evaporated per unit time and area *(g/m²h) in this paper expressed as evaporation rate (ER)*

been determined by indirect methods e g by measuring the flow and absolute humidity of the air supplied to and leaving the closed chamber in which the infant has been placed (10 25) or by gravimetric techniques (5 22 23 24) Using these methods it has been demonstrated that a relation exists between IWL and the relative humidity of the environment (10) that the water losses per surface unit are greater in infants with a low birth weight (5) and that a marked increase in the water losses takes place on exposure to radiant warmers (23)

When measuring water losses by placing the infant in a ventilated chamber it is necessary that the infant is in a good general condition and does not require nursing procedures during the period of measurement This measuring system is slow and technical problems easily arise through the presence of urine and meconium in the measurement chamber absorption of water in hygroscopic material condensation in tubing etc

Studies of water losses in very small low birth weight infants have therefore been carried out mostly by determination of the insensible weight loss (IL g/h) with body weighing Accurate results can only be obtained however when relatively long periods of measurement are used

IWL consists partly of the total cutaneous water loss (CWL g/h) and partly of water loss through the respiratory passages According to Hey & Katz (10) CWL comprises about 75% of IWL The cutaneous evaporative water loss is usually expressed per unit area and is then called transepidermal water loss (TEWL g/m²h) A selective study of TEWL in newborn infants, and its relation to environmental factors degree of activity and gestational age for example requires a method that allows

- direct measurement of the rate of evaporation from the skin surface
- free evaporation from the skin surface
- quick measurements
- repeated measurements at short intervals
- measurements of relatively rapid changes
- measurement without discomfort to the infant

An instrument that satisfies the above criteria and which measures the rate of evaporation from small skin surfaces has therefore been developed for use in neonatal care and other fields

In this paper the measurement technique employed will be briefly described The purpose of the first study using this technique in neonatal care was to investigate the evaporation rate from the skin of newborn infants at varying degrees of ambient humidity and from different surface areas of the body On the basis of the results obtained an easily handled way of estimating TEWL is proposed

Abbreviations

ER	= the locally measured rate of evaporation from the surface of the skin (g/m²h)
IL	= insensible loss of weight (g/h)
IWL	= insensible loss of water (g/h)
CWL	= total cutaneous water loss (g/h)
TEWL	= transepidermal water loss (g/m h)
Area	= area of a specified surface of the body (m²)
BSA	= total body surface area (m²)
H	= body height (m)
W	= body weight (kg)
$p_{H_2O\ amb}$	= ambient water vapour pressure (Pa)
RH_{amb}	= ambient relative humidity (%)
T_{amb}	= ambient temperature (°C)
T_{body}	= body temperature (°C)
T_{skl}	= skin temperature (°C)
$\frac{1}{A}\frac{dm}{dt}$	= evaporated amount of water per unit time and area (g/m²h)
D	= a constant 0 670 10⁻³ (g/mhPa)
$\frac{\delta p}{\delta x}$	= vapour pressure gradient (Pa/m)
$\dot{V}_{O_2}$	= oxygen consumption (g/h)
$\dot{V}_{CO_2}$	= carbon dioxide production (g/h)

SUBJECTS

Measurements of ER were performed on 78 healthy newborn infants born in the 38th–40th week of pregnancy The measurements were performed during the first 30 hours after delivery The infant's skin was not washed or wiped before the measurements In 19 infants (*Table 1*) ER was measured at varying ambient humidities (RH_{amb}) and in 9 infants (*Table 2*) ER was measured from different skin surfaces under constant environmental conditions The infants were often asleep when the measurements

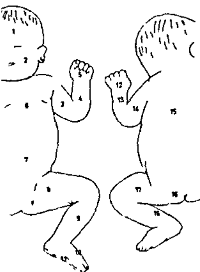

Fig 2 The measurement sites in series II

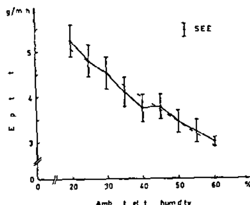

Fig 3 The relation between evaporation rate (ER) and ambient relative humidity (RH_{amb}) S E E = standard error of the estimate

65% or decreased from 60 to 0% through a change in the relation between dried and humidified air at a constant air flow Under Results values for each 5% change in RH are given At each RH level steady state was attained in the environmental factors after 5–10 min T_{amb} was kept as constant as possible (see Table 3)

II Measurement of ER from different skin surface areas
During these measurements RH_{amb} was maintained at about 50% and T_{amb} as constant as possible (see Table 4) The air supply to the incubator was kept constant at 8 l/min Measurements were performed with the infant prone supine and in the lateral position The skin surface areas examined are shown in Fig 2

TREATMENT OF DATA

The measurements gave data for ER RH_{amb} T_{sk} T_{amb} and T_{wall} In addition the vapour pressure of the ambient air ($P_{H_2O_{amb}}$) was calculated as the *product of the saturated* vapour pressure and the relative humidity which were measured in the incubator between every measurement of ER

When calculating ER for different $P_{H_2O_{amb}}$ values for ER at equidistant partial pressures (0 0 kPa) were obtained by linear interpolation between the actual measurement values for each individual infant

RESULTS

Evaporation rate at different ambient humidities

When ER was measured from an interscapular skin surface (site 15 in Fig 2) considerably higher values were obtained at a low RH_{amb} than at a high one (Fig 3) Thus ER at an RH_{amb} of 60% comprised only 60% of that measured at an RH_{amb} of 20% Measurements on six infants at an RH_{amb} of 65% gave even lower ER values (2 7 g/m²h) A linear relation between ER and RH_{amb} was obtained The coefficient of correlation between ER and RH_{amb} was −0 986 When ER was related to $P_{H_2O_{amb}}$ an essentially similar correlation was found (Fig 4) In this case the correlation coefficient was −0 971 Both modes of presentation have been chosen as RH is clinically the most commonly used parameter while $P_{H_2O_{amb}}$ is the most correct physically The

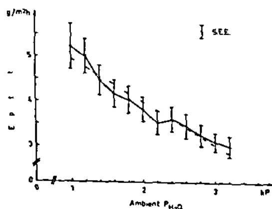

Fig 4 The relation between evaporation rate (ER) and ambient vapour pressure ($P_{H_2O_{amb}}$) S E E = standard error of the estimate

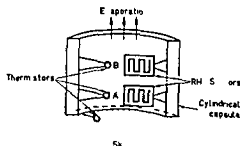

Fig 1 The arrangement of the sensors

D is a constant (0 670×10 ³ g/mhPa)
$\frac{\delta p}{\delta x}$ is the vapour pressure gradient of the water vapour (Pa/m)

This equation is valid in the immediate vicinity of the eva porative surface i e in the zone of diffusion which is about 10 mm wide At a constant rate of evaporation the vapour pressure in the diffusion zone decreases linearly with the distance from the skin surface

The vapour pressure gradient is therefore proportional to the difference in vapour pressure at two separate points (*A* and *B* in Fig 1) located on a line perpendicular to the evaporative surface The vapour pressure at the two measurement points is calculated as the product of the relative humidity and the saturated vapour pressure the latter being a function of the temperature alone According to equation 1 the water evaporation per unit time and area (ER) can then be calculated as a constant multiplied by the measured difference in vapour pressure between the two measurement points The arrangement of the different sensors over the skin section in question is illustrated in Fig 1

The relative humidity at each measurement point was measured by a small capacitive sensor of thin film type (Vaisala Humicap HMP11 Vaisala Oy Helsinki Finland) This sensor in addition to having adequate rapidity showed good linearity as well as long term stability

The saturated vapour pressure was calculated from the temperature at each measurement point As a temperature sensor a small fast thermistor was used (M81 Siemens AG Furth West Germany)

In order to maintain a stable zone of diffusion the measurement area was protected against circulating air currents with a teflon cylinder which could easily be withdrawn and sterilized

The vapour pressures in question and the difference between them were calculated in a specially constructed instrument (16 18) To obtain a stable ER value the signal was averaged in a low pass filter with a variable time constant

The instrument was supplied with a digital display for three digit read out Two ranges (00 0–99 9 and 000–999 g/m²h) could be selected Alternatively the relative humidity saturated vapour pressure and skin or air temperature could be displayed

The RH sensors were calibrated by placing them in air with known relative humidities produced in sealed boxes half filled with different saturated salt solutions (1)

The temperature of the skin area in question (T_{ski}) was measured with a separate thermistor (M81) attached to the teflon cylinder (Fig 1) but was also checked by a thermistor thermometer (YSI Model 43 Yellow Springs Ohio USA) The body temperature (T_{body}) was measured intermittently with a rectal thermometer The ambient temperature (T_{amb}) was measured in the middle of the incubator with a thermistor (M81) ER RH_{amb} T_{amb} and T_{ski} were registered in a recording system (Hokushin Electric Works Ltd Tokyo Japan)

MEASUREMENT PROCEDURE

All measurements were performed as described above with the newborn infant placed in an incubator (AGA MK41 AGA Medical Lidingo Sweden) At measurements with an air flow velocity meter (Type 8500 Thermo-anemometer Alnor Illinois USA) it was found that the air flow velocity inside the incubator was always below 15 cm/s The influence of this velocity on ER was tested by simultaneous measurements of the rate of evaporation by the described method and determination of the loss in weight of an evaporative salt solution placed on a balance inside the incubator When the fan of the incubator was turned off the weight loss of the salt solution per unit of time was reduced by 29% At the same time the measured ER decreased by 26% Consequently the air flow in the incubator caused only a small error of approximately 3% at measurements of ER from the skin surface of infants placed in an incubator when the fan was in function

The degree of influence of a low air flow velocity on the water loss from an evaporative surface found in this study is consistent with results of other investigators (20)

During the measurements T_{ski} T_{body} and T_{amb} were maintained within narrow limits T_{body} was 36 0–37 0°C in all cases This excluded sweating which according to Hey & Katz (10) does not occur at body temperatures below 37 2 C For all manipulations in the incubator during the measurement procedure the hands of the investigator were placed in airtight plastic bags carefully fixed in the openings of the incubator In this way exchange of air with air outside the incubator could be avoided during the measurement sequences

1 Measurement of ER at different ambient humidities

The infant was placed in an incubator in which the relative humidity could be varied by means of the humidifying system of the incubator and a dehumidifying system in which the air was dried by water absorbing lithium chloride (Munters Torkar AB Sollentuna Sweden) The flow of the dried air was checked with a respirometer (Wright Respirometer BOC Ltd Pinnacles UK) A total air supply (partly through the gas system of the incubator and partly through the dehumidifying system) of 15 l/min was used The dried air entered the incubator at a point immediately adjacent to the point of entry of air from the ordinary gas system of the incubator

During intermittent measurement of ER from an interscapular skin surface RH_{amb} was increased from 20 to

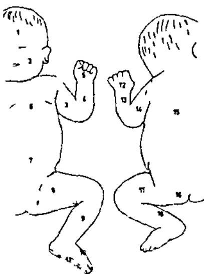

Fig 2 The measurement sites in series II

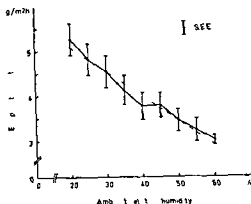

Fig 3 The relation between evaporation rate (ER) and ambient relative humidity (RH_{amb}) S E E = standard error of the estimate

65% or decreased from 60 to 0% through a change in the relation between dried and humidified air at a constant air flow Under Results values for each 5% change in RH are given At each RH level steady state was attained in the environmental factors after 5–10 min T_{am} was kept as constant as possible (see Table 3)

II Measurement of ER from different skin surface areas
During these measurements RH_{amb} was maintained at about 50% and T_{amb} as constant as possible (see Table 4) The air supply to the incubator was kept constant at 8 l/min Measurements were performed with the infant prone supine and in the lateral position The skin surface areas examined are shown in Fig

TREATMENT OF DATA

The measurements gave data for ER RH_{amb} T_{ski} T_{am} and T_{inc} In addition the vapour pressure of the ambient air ($P_{H_2O_{amb}}$) was calculated as the product of the saturated vapour pressure and the relative humidity which were measured in the incubator between every measurement of ER

When calculating ER for different $P_{H_2O_{amb}}$ values for ER at equidistant partial pressures (0 50 kPa) were obtained by linear interpolation between the actual measurement values for each individual infant

RESULTS

Evaporation rate at different ambient humidities

When ER was measured from an interscapular skin surface (site 15 in Fig 2) considerably higher values were obtained at a low RH_{amb} than at a high one (Fig 3) Thus ER at an RH_{amb} of 60% comprised only 60% of that measured at an RH_{amb} of 20% Measurements on six infants at an RH_{amb} of 65% gave even lower ER values (2 7 g/m²h) A linear relation between ER and RH_{amb} was obtained The coefficient of correlation between ER and RH_{amb} was −0 986 When ER was related to $P_{H_2O_{amb}}$ an essentially similar correlation was found (Fig 4) In this case the correlation coefficient was −0 971 Both modes of presentation have been chosen as RH is clinically the most commonly used parameter while $P_{H_2O_{amb}}$ is the most correct physically The

regression line ( ) has been drawn in both Fig 3 and Fig 4 Regressions of a higher order deviated very little from the linear function (Fig 4)

$$ER = -0.96\, P_{H_2O} + 5.90 \qquad (2)$$

This equation is based on measurements performed during both stepwise increases and stepwise decreases of P_{H_2O}

Changes in the water content of the incubator air did not give rise to changes in the skin and rectal temperatures or in the ambient temperature (Table 3)

Evaporation rate from different body surface areas

Measurements of ER were performed at 18 sites on the skin surface (Fig 2) selected so that all parts of the body were represented ER was particularly high on the forehead (site 1) and the palm of the hand (site 5) but was also high on the cheek (site 2) the upper arm (site 3) and the sole of the foot (site 11) (see Fig 5)

The areas of skin representing the largest proportion of the total body surface area gave lower ER values On the chest (site 6) and abdomen (site 7) ER were thus 5.2 and 3.8 g/m h on an interscapular area (site 15) the value was 8.2 g/m h and on the gluteal region (site 16) 9.1 g/m²h

During the measurements of ER at different sites on the body surface T_{body} T_{amb} and RH_{amb} were carefully controlled (Table 4) As seen in the table the regional differences in skin temperature were small

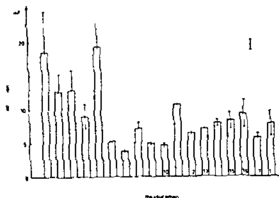

Fig 5 The evaporation rate (ER) from the 18 sites examined in series II (see Fig)

Estimation of the transepidermal water loss (TEWL)

By calculating the different areas of the body surface according to the linear formula of Du Bois (4 see also 2) and inserting the measured ER (Fig 5) into the equation

$$\mathrm{TEWL} = \frac{\sum_{i}^{i} \mathrm{ER}_i \ \mathrm{Area}_i}{\mathrm{BSA}} \qquad (3)$$

the mean evaporation (transepidermal water loss TEWL g/m h) was obtained The body surface area was calculated from Du Bois length-weight formula where the proportionality constant was changed in accordance with van Graan (7)

$$\mathrm{BSA} = 0\ 2157 W^{0\ 4\ 5}\ H^{0\ 7\ 5} \qquad (4)$$

where BSA is the body surface area (m²) H is the height (m) W is the weight of the infant (kg)

Using the above described method of calculation a mean value of 8 1 g/m²h was obtained for TEWL

For all infants the correlation between the arithmetic mean of ER from different combinations of a few measurement sites and TEWL calculated from equation (3) was tested Measurement sites 6 15 and 16 (Fig 2) gave a correlation coefficient of 0 945 (Fig 6) These sites represent a considerable proportion of the total body surface area Thus TEWL can be estimated with reasonable accuracy by measuring ER at a small number of sites using the equation

$$\mathrm{TEWL} = 0\ 92\,\overline{\mathrm{ER}}_{(6\ 15\ 16)} + 1\ 37 \qquad (5)$$

where $\overline{\mathrm{ER}}_{(6\ 15\ 16)}$ is the arithmetic mean of ER measured at three sites on the skin surface (sites 6 15 16) The total evaporative water loss from the entire skin surface (cutaneous water loss CWL g/h) is calculated as follows

$$\mathrm{CWL} = \mathrm{TEWL} \times \mathrm{BSA} \qquad (6)$$

regression line (-) has been drawn in both Fig 3 and Fig 4 Regressions of a higher order deviated very little from the linear function (Fig 4)

$$ER = -0\ 96\ P_{H_2O} \quad +5\ 90 \qquad (2)$$

This equation is based on measurements performed during both stepwise increases and stepwise decreases of P_{H_2O}

Changes in the water content of the incubator air did not give rise to changes in the skin and rectal temperatures or in the ambient temperature (Table 3)

Evaporation rate from different body surface areas

Measurements of ER were performed at 18 sites on the skin surface (Fig 2) selected so that all parts of the body were represented ER was particularly high on the forehead (site 1) and the palm of the hand (site 5) but was also high on the cheek (site 2) the upper arm (site 3) and the sole of the foot (site 11) (see Fig 5)

The areas of skin representing the largest proportion of the total body surface area gave lower ER values On the chest (site 6) and abdomen (site 7) ER were thus 5 2 and 3 8 g/m h on an interscapular area (site 15) the value was 8 2 g/m h and on the gluteal region (site 16) 9 1 g/m h

During the measurements of ER at different sites on the body surface T_{body} T_{amb} and RH_{amb} were carefully controlled (Table 4) As seen in the table the regional differences in skin temperature were small

$$\mathrm{CWL}=\mathrm{TEWL}\times\mathrm{BSA} \tag{6}$$

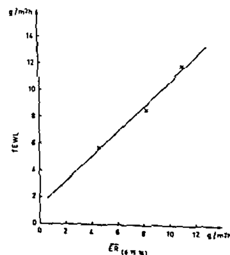

Fig 6 The relation between calculated transepidermal water loss (*TEWL*) and the arithmetic mean of the evaporation rate from the three skin sites 6 15 and 16

DISCUSSION

Newborn infants comprise a very heterogeneous group of individuals in which differences in birth weight and birth length gestational age and nutritional state for example are accompanied by differences in the state of hydration (6 19 21) and in the capacity to compensate for disturbances in the water balance (9 15) The treatment of such disturbances during neonatal intensive care has been discussed in numerous articles (3 19) Whereas the supply of fluid has been dealt with extensively the question of water loss has received less attention

The methods used for studies of IWL have been based either on measurement of changes in the water content of air flowing through a measurement chamber or on direct measurement of the infant s weight loss during a given period of time (IL) The former method however offers little possibility of studying infants who need nursing procedures during the relatively long measurement periods required As according to the Isenschmid equation (11) IL is not directly comparable to IWL ($IL = IWL + V_{CO} - V_O$) measurements based on weighing can give rise to an overestimation of IWL by about 10%

With the method described in this paper many of these difficulties have been overcome Direct measurement of ER has been possible without interference with normal nursing procedures Further the method has been found to satisfy demands for a high degree of accuracy a minimal influence on the examined skin surface and its ambient microclimate a short measurement time and a possibility of quickly repeated measurements The method differs in most respects from previously employed techniques for determination of the rate of evaporation from the skin surface (16)

This new method allows direct recording of changes in ER under varying external conditions (see Methods and Measurement Procedure) In the present investigation ER was studied during variations in the water content of the ambient air and a linear relation was found between ER and relative humidity at a constant ambient temperature At a high ambient humidity (60%) ER was about 60% of the value at a low humidity (20%) In previous similar investigations (10) employing indirect methods of measurement the basal transepidermal water loss was reported to be only about 30% lower at a high than at a low ambient humidity These discrepancies must be ascribed to methodological differences

In studies on adults variations in ER have been noted with a maximum at an ambient humidity of about 30% (8) Other investigators however have noted no difference in ER at varying humidities of the ambient air (13)

When measurements were made at different areas of the body surface at constant environmental conditions considerable differences in ER were found between the head and peripheral parts of the extremities in comparison with the trunk Analogous results were obtained in measurements on adult subjects at rest using the same method (12)

On calculation of TEWL from measured ER values a mean of 8 1 g/m h was obtained at an ambient humidity of 50% The value of 6 8 g/m²h reported by Hey & Katz (10) was obtained at an ambient humidity of about 60% Despite differences in the method of measurement and in environmental factors the results were thus fairly similar

On comparison between the ER at an interscapular skin surface (site 15) at an RH_{amb} of 50% in the measurement series I in which the ambient humidity was varied and the corresponding ER (site 15 RH_{amb} 50%) in series II a lower mean ER value was found in series I Several factors may have contributed to this difference For instance the infants examined in series I (Table 1) lay in the same position throughout the measurements while in series II (Table 2) the infants had to be turned to allow measurement on all sites depicted in Fig 2 Another factor which may have contributed to the higher ER in series II is the higher ambient temperature in that

series The difference in ambient temperature between series I and II was 1 2 C Equal body temperatures were obtained in the two series The skin temperature in the infants in series II was generally lower than that in series I This can be explained by an increased eva poration and a consequent increased heat loss from the skin

The possibility of using ER values from only a few different combinations of measurement sites for calculating TEWL was examined and a correlation coefficient of 0 945 was obtained between the calculated TEWL and the arith metic mean value of ER measured at sites 6 15 and 16 Thus TEWL can be estimated with reasonable accuracy by measuring ER at a small number of skin areas each representing large proportions of the total body surface area Applied in this way this new method allows a rapid estimation of ongoing trans epidermal water loss

CONCLUSIONS

In studies of transepidermal water loss in new born infants the method described in this paper has considerable advantages

1 Direct measurement of free evaporation from the skin surface can be performed at short intervals
2 The measurement procedure causes no dis comfort to the infant and does not interfere with routine nursing procedures
3 The method allows extensive studies of the influence of different factors on evapora tion from the skin surface
4 There is a linear relation between the am bient humidity and evaporation from the skin surface
5 The evaporation rate is dependent on the site of measurement
6 The total transepidermal water loss can be estimated by measurement at only a few selected skin areas

DISCUSSION

Newborn infants comprise a very heterogeneous group of individuals in which differences in birth weight and birth length, gestational age and nutritional state, for example, are accompanied by differences in the state of hydration (6, 19, 21) and in the capacity to compensate for disturbances in the water balance (9, 15). The treatment of such disturbances during neonatal intensive care has been discussed in numerous articles (3, 19). Whereas the supply of fluid has been dealt with extensively, the question of water loss has received less attention.

The methods used for studies of IWL have been based either on measurement of changes in the water content of air flowing through a measurement chamber or on direct measurement of the infant's weight loss during a given period of time (IL). The former method, however, offers little possibility of studying infants who need nursing procedures during the relatively long measurement periods required. As according to the Isenschmid equation (11), IL is not directly comparable to IWL ($IL = IWL + V_{CO_2} - V_{O_2}$), measurements based on weighing can give rise to an overestimation of IWL by about 10%.

With the method described in this paper many of these difficulties have been overcome. Direct measurement of ER has been possible without interference with normal nursing procedures. Further, the method has been found to satisfy demands for a high degree of accuracy, a minimal influence on the examined skin surface and its ambient microclimate, a short measurement time and a possibility of quickly repeated measurements. The method differs in most respects from previously employed techniques for determination of the rate of evaporation from the skin surface (16).

This new method allows direct recording of changes in ER under varying external conditions (see Methods and Measurement Procedure). In the present investigation ER was studied during variations in the water content of the ambient air, and a linear relation was found between ER and relative humidity at a constant ambient temperature. At a high ambient humidity (60%) ER was about 60% of the value at a low humidity (20%). In previous similar investigations (10) employing indirect methods of measurement, the basal transepidermal water loss was reported to be only about 30% lower at a high than at a low ambient humidity. These discrepancies must be ascribed to methodological differences.

In studies on adults variations in ER have been noted, with a maximum at an ambient humidity of about 30% (8). Other investigators, however, have noted no difference in ER at varying humidities of the ambient air (13).

When measurements were made at different areas of the body surface at constant environmental conditions, considerable differences in ER were found between the head and peripheral parts of the extremities in comparison with the trunk. Analogous results were obtained in measurements on adult subjects at rest using the same method (12).

On calculation of TEWL from measured ER values, a mean of 8.1 g/m²h was obtained at an ambient humidity of 50%. The value of 6.8 g/m²h reported by Hey & Katz (10) was obtained at an ambient humidity of about 60%. Despite differences in the method of measurement and in environmental factors, the results were thus fairly similar.

On comparison between the ER at an interscapular skin surface (site 15) at an RH_{amb} of 50% in the measurement series I, in which the ambient humidity was varied, and the corresponding ER (site 15, RH_{amb} 50%) in series II, a lower mean ER value was found in series I. Several factors may have contributed to this difference. For instance, the infants examined in series I (Table 1) lay in the same position throughout the measurements, while in series II (Table 2) the infants had to be turned to allow measurement on all sites depicted in Fig. 2. Another factor which may have contributed to the higher ER in series II is the higher ambient temperature in that

series The difference in ambient temperature between series I and II was 1 2 C Equal body temperatures were obtained in the two series The skin temperature in the infants in series II was generally lower than that in series I This can be explained by an increased evaporation and a consequent increased heat loss from the skin

The possibility of using ER values from only a few different combinations of measurement sites for calculating TEWL was examined and a correlation coefficient of 0 945 was obtained between the calculated TEWL and the arithmetic mean value of ER measured at sites 6 15 and 16 Thus TEWL can be estimated with reasonable accuracy by measuring ER at a small number of skin areas each representing large proportions of the total body surface area Applied in this way this new method allows a rapid estimation of ongoing transepidermal water loss

CONCLUSIONS

In studies of transepidermal water loss in new born infants the method described in this paper has considerable advantages

1 Direct measurement of free evaporation from the skin surface can be performed at short intervals
2 The measurement procedure causes no discomfort to the infant and does not interfere with routine nursing procedures
3 The method allows extensive studies of the influence of different factors on evaporation from the skin surface
4 There is a linear relation between the ambient humidity and evaporation from the skin surface
5 The evaporation rate is dependent on the site of measurement
6 The total transepidermal water loss can be estimated by measurement at only a few selected skin areas

On comparison between the ER at an interscapular skin surface (site 15) at an RH_{amb} of 50% in the measurement series I in which the ambient humidity was varied and the corresponding ER (site 15 RH_{amb} 50%) in series II a lower mean ER value was found in series I Several factors may have contributed to this difference For instance the infants examined in series I (Table 1) lay in the same position throughout the measurements while in series II (Table 2) the infants had to be turned to allow measurement on all sites depicted in Fig 2 Another factor which may have contributed to the higher ER in series II is the higher ambient temperature in that

series The difference in ambient temperature between series I and II was 1 2 C Equal body temperatures were obtained in the two series The skin temperature in the infants in series II was generally lower than that in series I This can be explained by an increased evaporation and a consequent increased heat loss from the skin

The possibility of using ER values from only a few different combinations of measurement sites for calculating TEWL was examined and a correlation coefficient of 0 945 was obtained between the calculated TEWL and the arithmetic mean value of ER measured at sites 6 15 and 16 Thus TEWL can be estimated with reasonable accuracy by measuring ER at a small number of skin areas each representing large proportions of the total body surface area Applied in this way this new method allows a rapid estimation of ongoing transepidermal water loss

CONCLUSIONS

In studies of transepidermal water loss in newborn infants the method described in this paper has considerable advantages

1 Direct measurement of free evaporation from the skin surface can be performed at short intervals
2 The measurement procedure causes no discomfort to the infant and does not interfere with routine nursing procedures
3 The method allows extensive studies of the influence of different factors on evaporation from the skin surface
4 There is a linear relation between the ambient humidity and evaporation from the skin surface
5 The evaporation rate is dependent on the site of measurement
6 The total transepidermal water loss can be estimated by measurement at only a few selected skin areas

ACKNOWLEDGEMENTS

The study was supported financially by grants from the Swedish Board of Technical Development Stockholm (project 74 387? 75 3615) and the Swedish Medical Research Council (projects B75 61P-4566-01 B77 19X 04998-01)

The authors wish to thank P Carlsson L Eriksson K Larsson C Nilsson H Pettersson and P Torngren for valuable contributions in the technical development B Östmark for skilful laboratory and technical assistance and E Ekstrom S G Nilsson S G Norberg and O Wistrand for expert technical assistance

The valuable help of B Bergman and her collaborators at the Neonatal Unit of the University Hospital Uppsala is also gratefully acknowledged

DISCUSSION

Newborn infants comprise a very heterogeneous group of individuals in which differences in birth weight and birth length gestational age and nutritional state for example are accompanied by differences in the state of hydration (6 19 21) and in the capacity to compensate for disturbances in the water balance (9 15) The treatment of such disturbances during neonatal intensive care has been discussed in numerous articles (3 19) Whereas the supply of fluid has been dealt with extensively the question of water loss has received less attention

The methods used for studies of IWL have been based either on measurement of changes in the water content of air flowing through a measurement chamber or on direct measurement of the infant s weight loss during a given period of time (IL) The former method however offers little possibility of studying infants who need nursing procedures during the relatively long measurement periods required As according to the Isenschmid equation (11) IL is not directly comparable to IWL (IL=IWL+ $V_{CO}-V_O$) measurements based on weighing can give rise to an overestimation of IWL by about 10%

With the method described in this paper many of these difficulties have been overcome Direct measurement of ER has been possible without interference with normal nursing procedures Further the method has been found to satisfy demands for a high degree of accuracy a minimal influence on the examined skin surface and its ambient microclimate a short measurement time and a possibility of quickly repeated measurements The method differs in most respects from previously employed techniques for determination of the rate of evaporation from the skin surface (16)

This new method allows direct recording of changes in ER under varying external conditions (see Methods and Measurement Procedure) In the present investigation ER was studied during variations in the water content of the ambient air and a linear relation was found between ER and relative humidity at a constant ambient temperature At a high ambient humidity (60%) ER was about 60% of the value at a low humidity (20%) In previous similar investigations (10) employing indirect methods of measurement the basal transepidermal water loss was reported to be only about 30% lower at a high than at a low ambient humidity These discrepancies must be ascribed to methodological differences

In studies on adults variations in ER have been noted with a maximum at an ambient humidity of about 30% (8) Other investigators however have noted no difference in ER at varying humidities of the ambient air (13)

When measurements were made at different areas of the body surface at constant environmental conditions considerable differences in ER were found between the head and peripheral parts of the extremities in comparison with the trunk Analogous results were obtained in measurements on adult subjects at rest using the same method (12)

On calculation of TEWL from measured ER values a mean of 8 1 g/m h was obtained at an ambient humidity of 50% The value of 6 8 g/m²h reported by Hey & Katz (10) was obtained at an ambient humidity of about 60% Despite differences in the method of measurement and in environmental factors the results were thus fairly similar

On comparison between the ER at an interscapular skin surface (site 15) at an RH_{amb} of 50% in the measurement series I in which the ambient humidity was varied and the corresponding ER (site 15 RH_{amb} 50%) in series II a lower mean ER value was found in series I Several factors may have contributed to this difference For instance the infants examined in series I (Table 1) lay in the same position throughout the measurements while in series II (Table 2) the infants had to be turned to allow measurement on all sites depicted in Fig 2 Another factor which may have contributed to the higher ER in series II is the higher ambient temperature in that

PLASMA DIAZEPAM IN INFANTS AFTER RECTAL ADMINISTRATION IN SOLUTION AND BY SUPPOSITORY

FINN URSIN KNUDSEN

From the Department of Paediatrics Glostrup Hospital Glostrup Denmark

ABSTRACT Knudsen F U (Department of Paediatrics Glostrup Hospital Glostrup Denmark) Plasma-diazepam in infants after rectal administration in solution and by suppository Acta Paediatr Scand 66 563 1977.—Twenty infants aged 1–2 years who had previously had one attack of febrile convulsions were randomly given a single dose of diazepam rectally either as a solution (0 7 mg/kg) or by suppository (5 mg) Plasma diazepam levels were determined repeatedly during the first hour using gas chromatography Rectal administration of diazepam in solution resulted in anticonvulsant plasma values within 4±1 min Similar plasma levels were obtained only after 20–30 min in the group treated with suppositories Diazepam in solution given rectally may therefore be useful in the acute treatment of febrile convulsions while treatment by suppository would seem to be of little value in this respect Moreover diazepam in solution given rectally seems suitable for use at home in case of recurrent febrile convulsions This treatment however cannot be recommended until the anticonvulsant effect and side-effects have been elucidated further

KEY WORDS Diazepam rectal administration plasma-diazepam anticonvulsant level febrile convulsions

The efficiency of diazepam as an anticonvulsant when administered intravenously is well documented (8 15 16 18 19 27) As this route is often unavailable especially in younger children with convulsive attacks other routes e g intramuscular (1 7 17 23) and rectal (1 2 21 23) have been attempted Thus Agurell et al (1) have recently shown that diazepam administered rectally in solution was quickly absorbed giving anticonvulsant plasma levels within minutes

The object of the present study was to determine plasma-diazepam levels following a single dose given rectally in solution or by suppository to 20 infants aged 1–2 years i e the age group with the highest incidence of febrile convulsions (14) The main purpose was to establish how fast anticonvulsant levels were achieved by the two methods

MATERIALS AND METHODS

The material (Table 1) comprised 20 infants aged 10–24 months The infants were admitted to our paediatric department with their first attack of febrile convulsions Informed consent was obtained from the parents who were later told of the results The infants were randomly allocated to one of two groups A and B Group A (10 infants) was given a suppository that contained 5 mg diazepam (Stesolid® suppository Dumex) while group B (10 infants) received a diazepam solution for rectal use (Apozepam® solution for rectal use Apothekernes Laboratorium for Specialpræparater) given with a plastic syringe connected to a 5 cm long plastic tube No attempt was made to evacuate the rectum prior to the administration Group A received a mean dose of 0 5 mg/kg (range 0 4–0 6 mg/kg) group B 0 7 mg/kg All infants were studied in a seizure free interval None had received benzodiazepine derivatives for two weeks prior to the study Ten infants (6 in group A 4 in group B) who were examined shortly after the attack of febrile convulsions had received a single dose of phenobarbital (3 mg/kg i m) 4–1 hours before The remainder who were tested in the outpatient clinic at an average of one month after the convulsions had received no anticonvulsant treat

Had received phenobarbital (see text)

(Case no 17 Table 3) had febrile convulsions at a plasma level of 1 185 ng/ml which is considered far above the anticonvulsant level

DISCUSSION

The study showed that diazepam when administered rectally in solution to infants without convulsions resulted in anticonvulsant plasma levels within 4±1 min This route of administration thus seems useful in the acute treatment of febrile convulsions and a valuable alternative to the intravenous route which might be unavailable

Our results confirm Agurell and coworker s (1) observations However the age and dose range in their series was much greater than ours The present study was aimed more specifically at the age group with the highest incidence of febrile convulsions Moreover the dose of diazepam was kept more constant Our peak level (1 449 ng/ml) is higher than reported by Agurell et al (516 ng/ml) which is presumably because they used smaller doses

The study also demonstrated that in the acute situation diazepam suppositories may well be ineffective compared with the solution as anticonvulsant levels are reached very slowly (1 2 21 23) Diazepam when given rectally in solution also seems more reliable than diazepam given i m the absorption from the muscle appears unpredictable (7) and the therapeutic level is not reached until about 10 min (1) 30 min (23) or more than 60 min (17) after the i m injection

Our knowledge of the correlation between plasma level and anticonvulsant effect of diazepam is based on very few observations (1 8 26) The anticonvulsant level used (Fig 1) has therefore been chosen on a somewhat arbitrary basis Following the intravenous administration of diazepam given for seizure control there is a rapid fall of the high plasma levels (1 8 13) and convulsions may recur

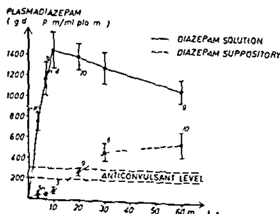

Fig 1 The mean values of plasma diazepam following administration by suppository (5 mg) (broken line) or in solution (0 7 mg/kg) (solid line) The vertical lines are S E of mean The suggested anticonvulsant plasma level of diazepam are 00–300 ng/ml n number of infants tested

Solution	10	17	12–24	10.9	8.7–15.5	0.7	0.7

ment for at least 3 weeks. At the time of the study 17 infants had a rectal temperature ≤37.0°C, two had 38.0–38.5 C and one had 40.0°C.

Analytical method

Blood samples (300 μl) for diazepam analysis were drawn by heel puncture in heparinized capillary blood collecting tubes. Whenever possible samples were taken at 4±1, 7±1, 10±2, 20±5, 30±5 and 60±5 min after diazepam administration. Within 1½ hours the blood was centrifuged and the plasma collected in two 50 μl micro pipets and stored at −20°C until analysed.

Diazepam and its main metabolite N desmethyl diazepam were determined in 50 μl samples of plasma by gas chromatography (4) by Apothekernes Laboratorium for Specialpræparater, Oslo, Norway. It was carried out with a 3% OV 17 column and a ^{63}Ni electron capture detector. Most samples were analysed in duplicate. The study was blind for the laboratory.

Clinical observation

The occurrence of side effects was noted.

One patient (no. 17, Table 3) developed febrile (40.0°C) universal clonic seizures and jittering lasting 4½ min. The convulsions took place 65 min after giving diazepam in solution and was observed by the author.

Statistical method

p Values were obtained by means of the Student's *t* test.

RESULTS

Plasma levels of diazepam are shown in Table 2 and 3 and also illustrated in Fig. 1.

Following the administration of 5 mg of diazepam as a suppository the anticonvulsant plasma level (probably in the region 200–300 ng diazepam/ml plasma (1, 8, 26)) was achieved after 20–30 min (Table 2). After one hour a mean plasma level of 564 ng/ml was reached (Fig. 1, Table 2).

Following rectal administration of diazepam in solution anticonvulsant plasma levels were reached in all 10 infants within 4±1 min (Fig. 1, Table 3). At that time the mean plasma value was 754 ng/ml. The mean peak level (1 449 ng/ml) was achieved within 20 min (range 1 020–2 610 ng/ml) (Table 3). Anticonvulsant levels were maintained for at least one hour (Fig. 1).

The plasma values at any point were significantly higher in the group of infants treated with diazepam in solution as compared with the group treated by suppository ($p<0.001$).

In all analyses the levels of N desmethyl diazepam in plasma were zero or less than 50 ng/ml, when corrected for the background level, which in healthy untreated adults was 50–100 ng/ml using this method.

Plasma diazepam was not influenced by previous administration of phenobarbital. This applies to the treatment by suppository ($p>0.2$) as well as solution ($p>0.2$) (Table 4).

No serious side effects were seen. The respiration appeared normal in all infants. Most became somewhat sedated and some also developed a transient ataxia. One patient

ment for at least 3 weeks At the time of the study 17 infants had a rectal temperature ≤37.0°C two had 38.0–38.5 C and one had 40.0°C

Analytical method

Blood samples (300 μl) for diazepam analysis were drawn by heel puncture in heparinized capillary blood collecting tubes Whenever possible samples were taken at 4±1 7±1 10±2 20±5 30±5 and 60±5 min after diazepam administration Within 1½ hours the blood was centrifuged and the plasma collected in two 50 μl micro pipets and stored at −20°C until analysed

Diazepam and its main metabolite N desmethyl diazepam were determined in 50 μl samples of plasma by gas chromatography (4) by Apothekernes Laboratorium for Specialpræparater Oslo Norway It was carried out with a 3% OV 17 column and a ^{63}Ni electron capture detector Most samples were analysed in duplicate The study was blind for the laboratory

Clinical observation

The occurrence of side effects was noted

One patient (no 17 Table 3) developed febrile (40.0°C) universal clonic seizures and jittering lasting 4½ min The convulsions took place 65 min after giving diazepam in solution and was observed by the author

Statistical method

p Values were obtained by means of the Student's t test

RESULTS

Plasma levels of diazepam are shown in Table 2 and 3 and also illustrated in Fig. 1

Following the administration of 5 mg of diazepam as a suppository the anticonvulsant plasma level (probably in the region 200–300 ng diazepam/ml plasma (1 8 26)) was achieved after 20–30 min (Table 2) After one hour a mean plasma level of 564 ng/ml was reached (Fig. 1 Table 2)

Following rectal administration of diazepam in solution anticonvulsant plasma levels were reached in all 10 infants within 4±1 min (Fig. 1 Table 3) At that time the mean plasma value was 754 ng/ml The mean peak level (1 449 ng/ml) was achieved within 20 min (range 1 020–2 610 ng/ml) (Table 3) Anticonvulsant levels were maintained for at least one hour (Fig. 1)

The plasma values at any point were significantly higher in the group of infants treated with diazepam in solution as compared with the group treated by suppository ($p<0.001$)

In all analyses the levels of N desmethyl diazepam in plasma were zero or less than 50 ng/ml when corrected for the background level which in healthy untreated adults was 50–100 ng/ml using this method

Plasma diazepam was not influenced by previous administration of phenobarbital This applies to the treatment by suppository ($p>0.2$) as well as solution ($p>0.2$) (Table 4)

No serious side effects were seen The respiration appeared normal in all infants Most became somewhat sedated and some also developed a transient ataxia One patient

Had received phenobarbital (see text)

(Case no 17 Table 3) had febrile convulsions at a plasma level of 1 185 ng/ml which is considered far above the anticonvulsant level

DISCUSSION

The study showed that diazepam when administered rectally in solution to infants without convulsions resulted in anticonvulsant plasma levels within 4±1 min This route of administration thus seems useful in the acute treatment of febrile convulsions and a valuable alternative to the intravenous route which might be unavailable

Our results confirm Agurell and coworker s (1) observations However the age and dose range in their series was much greater than ours The present study was aimed more specifically at the age group with the highest incidence of febrile convulsions Moreover the dose of diazepam was kept more constant Our peak level (1 449 ng/ml) is higher than reported by Agurell et al (516 ng/ml) which is presumably because they used smaller doses

The study also demonstrated that in the acute situation diazepam suppositories may well be ineffective compared with the solution as anticonvulsant levels are reached very slowly (1 2 21 23) Diazepam when given rectally in solution also seems more reliable than diazepam given i m the absorption from the muscle appears unpredictable (7) and the therapeutic level is not reached until about 10 min (1) 30 min (23) or more than 60 min (17) after the i m injection

Our knowledge of the correlation between plasma level and anticonvulsant effect of diazepam is based on very few observations (1 8 26) The anticonvulsant level used (Fig 1) has therefore been chosen on a somewhat arbitrary basis Following the intravenous administration of diazepam given for seizure control there is a rapid fall of the high plasma levels (1 8 13) and convulsions may recur

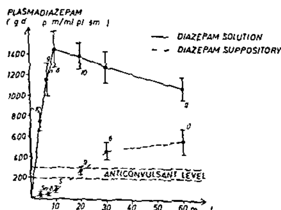

Fig 1 The mean values of plasma diazepam following administration by suppository (5 mg) (broken line) or in solution (0 7 mg/kg) (solid line) The vertical lines are S E of mean The suggested anticonvulsant plasma level of diazepam are ?00–300 *rg/ml n* number of infants tested

Table 4. *Influence of phenobarbital (3 mg/kg i.m.) on plasma levels of diazepam (mean values in ng/ml) administered by suppository and in solution*

Diazepam	Phenobarbital	No. of patients	Min after diazepam administration 4±1	7±1	10±2	20±5	30±5	60±5	p
Suppository	+	6	80	55	92	293	396	447	>0.2
Suppository	−	4	28	51	88	248	549	739	
Solution	+	4	728	1 238	1 730	1 578	1 385	860	>0.2
Solution	−	6	772	1 129	1 281	1 263	1 229	1 185	

within ½–1 hour (15, 18, 27). We observed febrile convulsions with a plasma diazepam level of nearly 1 200 ng/ml. Convulsions at a similarly high plasma level has not previously been reported.

One study seems to indicate that phenobarbital may stimulate the metabolism of diazepam (26). The doses of phenobarbital used in this study did not influence the plasma levels of diazepam.

The plasma values of N-desmethyl diazepam was negligible, because the desmethylation is a slow process in the human being (10). The anticonvulsant properties of the metabolite therefore is of no importance in acute seizure control.

Diazepam administered rectally in solution seems suitable for use in recurrent febrile convulsions and treatment may be given by the parents at home. The procedure is simple and a high plasma level of diazepam is quickly reached. Moreover diazepam is remarkably free from undesirable effects (6, 11, 12, 20, 24). Serious side effects (3) or death (16, 19, 27) have only been reported a few times and a simple cause and effect relationship could not be established in these cases (5, 11, 22, 25).

The plasma levels reported here seem unduly high. The doses should be reduced to 0.5 mg/kg if the treatment is to take place at home. This would reduce the peak level but also shorten the duration of effect (9). Before the treatment can be recommended for use at home it must be investigated further with regard to effect and side effects.

PERSISTENCE OF IN VITRO LYMPHOCYTE RESPONSE TO TUBERCULIN IN SKIN TEST NEGATIVE CHILDREN IMMUNIZED WITH BCG IN INFANCY

Z SPIRER E ASSIF V ZAKUTH N BOGAIR
J SCHWARTZ and M MENDES

From the Paediatric Department A Rokach (Hadassah) Hospital Tel Aviv the Department of Immunology Tel Aviv University Medical School and the Y Khassis Pulmonary Diseases Prevention Centre Ministry of Health Jaffa Israel

ABSTRACT Spirer Z Assif E Zakuth V and Bogair N (Paediatric Department A Rokach (Hadassah) Hospital Tel Aviv) Schwartz J (Department of Immunology Tel Aviv University Medical School Tel Aviv) and Mendes M (Y Khassis Pulmonary Diseases Prevention Centre Ministry of Health Jaffa Israel) Persistence of in vitro lymphocyte response to tuberculin in skin test negative children immunized with BCG in infancy Acta Paediatr Scand 66 569 1977.—PPD stimulated lymphocyte reactivity was tested in 119 children aged 11 to 12 years The lymphocyte responses was evaluated by measuring the extent of tritiated thymidine incorporation by cultured cells In a group of sixty four tuberculin negative children who had been BCG vaccinated in the neonatal period lymphocyte response was significantly greater than in a group of non vaccinated tuberculin negative children matched for sex The highest reactivity appeared in another group of children vaccinated in infancy and tuberculin positive Lymphocytes from BCG vaccinated children retain some sensitivity to tuberculin even years after the BCG vaccination and even at the time when the skin reactivity disappeared

KEY WORDS BCG vaccination lymphocyte response tuberculin test

Although the need and prophylactic value of BCG vaccination in control of tuberculosis is a source of controversy (1 11 12) there are countries where the policy is a routine vaccination of all infants Israeli children (excluding those in the Jerusalem area) are vaccinated routinely at the maternity hospital (4) At the age of 11 to 12 years all the children are tested with 2 PPD units and if a negative skin test is noted revaccinated (2 7)

Since a negative skin test is an accepted criterion for BCG revaccination we have therefore investigated the correlation between the skin test and the lymphocyte reactivity to PPD *in vitro* in vaccinated and non vaccinated children at this age

MATERIALS AND METHODS

Sixty four children who had been vaccinated at birth with BCG[1] were examined at the age of 11 to 12 years All of them were found to be non reacting to the tuberculin test in doses of PPD up to 50 T U In thirty nine children (Group I) the skin tests were performed before the *in vitro* studies in twenty five children (Group II) the *in vitro* study preceded the skin tests

Thirty children were non vaccinated (from Jerusalem area and of the same socio-economic status) and tuberculin negative (Group III) Twenty five children were tuberculin positive (to 5 T U) all of them having been vaccinated at birth (Group IV)

All the children were healthy with no personal or familial history of tuberculosis They were equally distributed as to sex and age

10 ml heparinized[2] blood was withdrawn from the cubital vein and allowed to sediment at room temperature

PERSISTENCE OF IN VITRO LYMPHOCYTE RESPONSE TO TUBERCULIN IN SKIN TEST NEGATIVE CHILDREN IMMUNIZED WITH BCG IN INFANCY

Z SPIRER E ASSIF V ZAKUTH N BOGAIR
J SCHWARTZ and M MENDES

From the Paediatric Department A Rokach (Hadassah) Hospital Tel Aviv the Department of Immunology Tel Aviv University Medical School and the Y Khassis Pulmonary Diseases Prevention Centre Ministry of Health Jaffa Israel

ABSTRACT Spirer Z Assif E Zakuth V and Bogair N (Paediatric Department A Rokach (Hadassah) Hospital Tel Aviv) Schwartz J (Department of Immunology Tel Aviv University Medical School Tel Aviv) and Mendes M (Y Khassis Pulmonary Diseases Prevention Centre Ministry of Health Jaffa Israel) Persistence of in vitro lymphocyte response to tuberculin in skin test negative children immunized with BCG in infancy Acta Paediatr Scand 66 569 1977.—PPD stimulated lymphocyte reactivity was tested in 119 children aged 11 to 12 years The lymphocyte responses was evaluated by measuring the extent of tritiated thymidine incorporation by cultured cells In a group of sixty four tuberculin negative children who had been BCG vaccinated in the neonatal period lymphocyte response was significantly greater than in a group of non vaccinated tuberculin negative children matched for sex The highest reactivity appeared in another group of children vaccinated in infancy and tuberculin positive Lymphocytes from BCG vaccinated children retain some sensitivity to tuberculin even years after the BCG vaccination and even at the time when the skin reactivity disappeared

KEY WORDS BCG vaccination lymphocyte response tuberculin test

Although the need and prophylactic value of BCG vaccination in control of tuberculosis is a source of controversy (1 11 12) there are countries where the policy is a routine vaccination of all infants Israeli children (excluding those in the Jerusalem area) are vaccinated routinely at the maternity hospital (4) At the age of 11 to 12 years all the children are tested with 2 PPD units and if a negative skin test is noted revaccinated (2 7)

Since a negative skin test is an accepted criterion for BCG revaccination we have therefore investigated the correlation between the skin test and the lymphocyte reactivity to PPD *in vitro* in vaccinated and non vaccinated children at this age

MATERIALS AND METHODS

Sixty four children who had been vaccinated at birth with BCG[1] were examined at the age of 11 to 12 years All of them were found to be non reacting to the tuberculin test in doses of PPD up to 50 T U In thirty nine children (Group I) the skin tests were performed before the *in vitro* studies in twenty five children (Group II) the *in vitro* study preceded the skin tests

Thirty children were non vaccinated (from Jerusalem area and of the same socio-economic status) and tuberculin negative (Group III) Twenty five children were tuberculin positive (to 5 T U) all of them having been vaccinated at birth (Group IV)

All the children were healthy with no personal or familial history of tuberculosis They were equally distributed as to sex and age

10 ml heparinized[2] blood was withdrawn from the cubital vein and allowed to sediment at room temperature

[2] Heparin Fluka

37-77 875

for one hour The leucocytes were separated by standard methods and cell rich plasma obtained The response was measured by the method of Valentine (14) using homologous sera in medium M E M 199 The cells (one million) were cultured with 20 μg PPD [1] with parallel blank controls and cultures with P H A [2] All cultures were done in triplicate After 72 hours of incubation 2 μc of tritiated thymidine were added to each tube Incorporation of the tritiated thymidine by the cultured cells was measured in a liquid scintillation counter and expressed in CPM/10^6 cells

RESULTS

The results are summarized in Table I In Group I the mean was 18 000±1 500 (±S E M) with a range from 6 000 to 42 000 Group II was very similar mean 18 500±1 600 (±S E M) range 6 800 to 38 000 Thus the skin testing with PPD preceding the culture had apparently no effect on the lymphocyte reactivity in this small series

In Group III non vaccinated and non reacting to tuberculin the mean value was 5 600± 1 200 (±S E M) with a range from 4 000 to 11 000

In Group IV the mean value was 32 000± 2 700 (±S E M) with a range from 12 000 to 58 000

There is a statistically significant difference ($p<0\ 05$) between Groups I and II and Group III on the one hand and Group IV on the other The difference between Groups III and IV is more significant ($p<0\ 002$)

DISCUSSION

There is evidence that lymphocyte stimulation assay may provide a sensitive and valuable indicator of exposure occult infection or a carrier state in some infectious diseases PPD is known to be a stimulator of lymphocyte transformation *in vitro* (8) It has been found active in cultures of cells from individuals with healed tuberculosis as well as those immunized with BCG

Table I *Lymphocyte response to PPD*

Groups I and II BCG vaccinated PPD-negative Group III non vaccinated PPD negative Group IV vaccinated PPD positive

Group	No of patients	Lymphocyte thymidine incorporation (CPM)	
		Mean±S E M	Range
I	39	18 000±1 500	6 000–42 000
II	25	18 500±1 600	6 800–38 000
III	30	5 600±1 200	4 000–11 000
IV	25	32 000±2 700	12 000–58 000

Generally a correlation is found between *in vitro* transformation and *in vivo* reactions to tuberculin despite wide variations in the *in vitro* results (3) Matsaniotis et al (5) found a relationship between *in vitro* response and a history of healed tuberculosis or BCG vaccination even in subjects negative to tuberculin in the skin test Another study (9) revealed that the *in vitro* response always precedes the conversion of the skin test However Thomas et al (13) found no relationship between these two phenomena in BCG vaccinated subjects

The wide range of the values as seen in our study makes the count of the PPD reactivity of lymphocytes an unreliable test in an individual examination Nevertheless when groups are examined our results show that in the vaccinated children 11 to 12 years after the BCG injection the lymphocytes still respond to PPD even when the skin reactivity had disappeared Children with a positive tuberculin reaction have the highest values of lymphocyte reactivity when stimulated with PPD

Although we cannot exclude the possible role of infection by nonpathogenic mycobacteria in maintaining a positive lymphocyte response our observations support the view that children vaccinated at birth may retain protection even though their skin reactivity has disappeared or markedly diminished It confirms the effectiveness of routine BCG vaccination of the newborn infants On the other hand it

THE GASTROINTESTINAL ABSORPTION OF PENICILLIN V IN CHILDREN WITH SUSPECTED COELIAC DISEASE

P BOLME M ERIKSSON and G STINTZING

From the Department of Paediatrics St Goran s Hospital Stockholm Sweden

ABSTRACT Bolme P Eriksson M and Stintzing G (Department of Paediatrics St Goran s Hospital Stockholm Sweden) The gastrointestinal absorption of penicillin V in children with suspected coeliac disease Acta Paediatr Scand 66 573 1977.—The gastrointestinal absorption of penicillin V (pc V) was investigated in 6 children 6–12 months old with suspected coeliac disease The diagnosis was set after small bowel biopsy and absorption tests of vitamin A and *d* xylose As control groups served 7 children with diarrhoea but with normal small bowel biopsy and/or absorption tests and a group of 9 children with upper respiratory tract infection of the same ages as the children in the test group The absorption of calcium pc V in oil suspension (Penicals®) was impaired in the patients with suspected coeliac disease compared to that of the control groups There was no significantly different absorption of pc V between the control children with diarrhoea and those with upper respiratory tract infection After 6–8 months of gluten free diet in the children with suspected coeliac disease their absorptive ability of oral calcium pc V in suspension form was equal with that of a control group

KEY WORDS Coeliac disease gastrointestinal absorption penicillin V *d* xylose vitamin A small bowel biopsy

Penicillin V (pc V) remains the drug of choice when bacterial infection in the respiratory tract is suspected in children For a clinical effect it is necessary that a concentration of penicillin high enough is achieved at the site of infection

Infants under the age of one year have been reported to absorb pc V to the same degree as adults but to have a more sustained plasma concentration probably due to immature kidney function (6 16) In a recent study from our laboratory it has been shown that diarrhoea of short duration does not influence the absorption of pc V and ampicillin while the absorption of pc V was markedly reduced in patients where the diarrhoea had lasted for a longer period and coeliac disease was suspected (1 2) These findings were in accordance with reports of low plasma levels of ampicillin after oral administration in children with bacterial gastroenteritis or shigellosis (4 13)

Parson and collegues (15) reported that adult patients with coeliac disease absorbed certain drugs to a less degree than healthy volonteers did No absorption study has been done in children when the diagnosis of coeliac disease is initially suspected Pc V was not among the drugs studied by Parson et al (15) but Davis & Pirola (3) reported that three adult patients with gluten induced enteropathy failed to absorb pc V and they compared the absorption with that of other patients with steatorrhoea from reasons other than coeliac disease Therefore we wished to study the gastrointestinal absorption of pc V in children with suspected coeliac disease and to follow their absorption during the healing phase when they were avoiding gluten in their diet

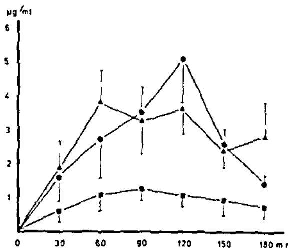

Fig 1 Plasma concentration (mean ±S E M) of penicillin after oral administration of 20 mg/kg b w of calcium penicillin V (Penicals®) in oil suspension Comparison *between control children (6–12 months)* ●—● *(n=9)* children with suspected coeliac disease ■—■ (n=6) and children with a history of diarrhoea but where the diagnosis of coeliac disease was ruled out ▲—▲ (n=7)

MATERIALS AND METHODS

Thirteen infants 6–12 months old referred to the hospital because of long lasting diarrhoea and with clinical signs of malabsorption were included in the study

On admission a careful history was taken concerning symptoms of diarrhoea and poor weight gain in relation to the introduction of gluten containing diet The time which had elapsed between introduction of gluten containing food and admission was relatively short (2–5 months) After clinical examination all children were given a test meal using simultaneous oral administration of *d* xylose glucose vitamin A and triglycerides (14) During the initial diagnostic investigations the gastrointestinal absorption of calcium pc V (Penicals®) was also determined Calcium pc V was given after at least two hours of fasting in the commercially available oil suspension in a dose of 20 mg/kg b w The absorption was judged by determining the plasma concentration of pc V at 30 min intervals for three hours When there was a strong clinical suspicion of coeliac disease or if the test meal revealed an impaired absorption of *d* xylose and/or vitamin A we performed a small bowel biopsy using the paediatric Crosby Kugler capsule *The biopsy specimen* was then examined in dissecting as well as in light microscope

The criteria for the diagnosis suspected coeliac disease were 1) clinical signs and symptoms 2) atrophy of the small intestinal mucosa i e a relative absence of villi

Following the criteria mentioned above the initial 13 children could be divided into two groups

1) Six patients with signs and symptoms suggesting the diagnosis of coeliac disease

2) Seven children with a history of diarrhoea but with a normal test meal and a normal intestinal mucosa if examined

As control group for the absorption of pc V served children who were prescribed pc V because of upper respiratory tract infection The control children were selected so that they were of the same age as the tested children None of the children in the control group had diarrhoea on the day when their pc V absorption was tested

In two infants with suspected coeliac disease the absorption of 20 mg/kg b w of calcium pc V was compared with that of 40 mg/kg b w of the same preparation

The plasma concentration of penicillin was determined using a microbiological method Ten µl of the patients plasma applied on a paper disc was put on Bacto Antibiotic Medium 5 (Difco) and the growth inhibiting capacity of *Sarcina Lutea* was determined The method has earlier been described in detail (1 7)

After the initial diagnostic measures the six infants where coeliac disease was suspected were prescribed a gluten free diet Repeated determination of the absorption of orally administered pc V was done in these six children *after 2–3 months on diet After 6–8 months they were* once again admitted for clinical examination and repeated small bowel biopsy was performed to check the histological improvement of the mucosa A test meal was given also at this occasion and the absorption of pc V was determined

RESULTS

In Fig 1 are shown the plasma concentrations of pc-V after the administration of 20 mg/kg b w of calcium pc V suspension to 1) Control patients which were children prescribed pc V because of upper respiratory tract infections 2) Children with suspected coeliac disease before diet and 3) infants admitted be

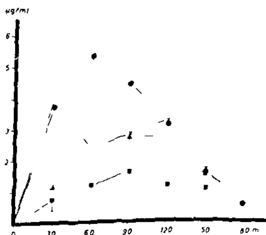

Fig 2 Plasma concentration (mean ±S E M) of penicillin after oral administration of 20 mg/kg b w of calcium pc V (Penicals®) in oil suspension Comparison between control children *(12–24 months)* ●—● *(n=6) and* patients with suspected coeliac disease (n=6) before diet ■—■ after 2 months of diet ▲—▲ and after 6–8 months of diet ×—×

cause of a history of diarrhoea but where the diagnosis of coeliac disease could be ruled out after diagnostic investigations

The six patients with suspected coeliac disease showed lower plasma concentrations of penicillin than the control group The differences in plasma concentrations between these two groups were statistically significant at 90 min ($p<0.01$) 120 and 150 min ($p<0.05$) The children admitted because of diarrhoea but where the diagnosis of coeliac disease could be ruled out showed no significant impairment of the absorption capacity of calcium pc V compared to the control group

The gastrointestinal absorption of calcium pc V in the six patients with suspected coeliac disease gradually improved on a gluten free diet as illustrated in Fig 2 After 6–8 months on diet the plasma concentrations of pc V were almost reaching the levels of those of the controls which were patients of the same age as the test group children after 6–8 months on diet

In Table 1 the individual children with suspected coeliac disease are listed The histological appearance of the small intestinal mucosa the absorption of vitamin A and *d* xylose in the test meal as well as the absorption of calcium pc V are presented The villous atrophy of the small intestinal mucosa is described as slight moderate or subtotal The absorption of vitamin A is classified as normal if a plasma level of 500 IU/100 ml was reached

Table 1 *Patients with suspected coeliac disease*

Small bowel biopsy vitamin A *d* xylose and penicillin V absorption

Patient	Small bowel biopsy (degree of atrophy)	Absorption tests: Vita min A	*d* xylose	Penicil lin V
HR	Moderate	Normal	Normal	Patol
CMW	Subtotal	Normal	Normal	Normal
CA	Slight	Patol	Patol	Normal
RLN	Subtotal	Patol	Patol	Patol
FS	Moderate	Patol	Patol	Patol
DH	Moderate	Patol	Patol	Normal

within 6 hours (8) The absorption of *d* xylose given in the test meal was regarded as normal if a plasma level of 20 mg/100 ml was reached within 3 hours The absorption of calcium pc V is listed as pathologic if the plasma concentration at 30–90 min was below −1 S D of the mean value for the control group As can be seen from Table 1 there was no definite correlation between degree of atrophy of the mucosa and the results of the absorption tests

Table 2 presents the same patients as in Table 1 after 6–8 months on a strict gluten free diet As can be seen three out of the six patients had a normal intestinal mucosa in two of the children the degree of atrophy of the mucosa had diminished Only one child had an unchanged mucosa This child (HR) was shown to have in addition a cow s milk protein intolerance and not until cow milk was totally excluded from the diet the intestinal mucosa showed healing

In Table 3 is shown the individual children with long lasting diarrhoea where the diagnosis of coeliac disease was ruled out As can be seen two of the seven children had a decreased absorption of pc V

By doubling the dose from 20 to 40 mg/kg b w of calcium pc V a higher plasma concentration of penicillin could be found in two children with suspected coeliac disease as shown in Fig 3

Table 2 *Patients with suspected coeliac disease*

MATERIALS AND METHODS

Thirteen infants 6–12 months old referred to the hospital because of long lasting diarrhoea and with clinical signs of malabsorption were included in the study

On admission a careful history was taken concerning symptoms of diarrhoea and poor weight gain in relation to the introduction of gluten containing diet The time which had elapsed between introduction of gluten containing food and admission was relatively short (2–5 months) After clinical examination all children were given a test meal using simultaneous oral administration of *d* xylose glucose vitamin A and triglycerides (14) During the initial diagnostic investigations the gastrointestinal absorption of calcium pc V (Pencals®) was also determined Calcium pc V was given after at least two hours of fasting in the commercially available oil suspension in a dose of 20 mg/kg b w The absorption was judged by determining the plasma concentration of pc V at 30 min intervals for three hours When there was a strong clinical suspicion of coeliac disease or if the test meal revealed an impaired absorption of *d* xylose and/or vitamin A we performed a small bowel biopsy using the paediatric Crosby Kugler capsule The biopsy specimen was then examined in dissecting as well as in light microscope

The criteria for the diagnosis suspected coeliac disease were 1) clinical signs and symptoms 2) atrophy of the small intestinal mucosa i e a relative absence of villi

Following the criteria mentioned above the initial 13 children could be divided into two groups

1) Six patients with signs and symptoms suggesting the diagnosis of coeliac disease

2) Seven children with a history of diarrhoea but with a normal test meal and a normal intestinal mucosa if examined

As control group for the absorption of pc V served children who were prescribed pc V because of upper respiratory tract infection The control children were selected so that they were of the same age as the tested children None of the children in the control group had diarrhoea on the day when their pc V absorption was tested

In two infants with suspected coeliac disease the absorption of 20 mg/kg b w of calcium pc V was compared with that of 40 mg/kg b w of the same preparation

The plasma concentration of penicillin was determined using a microbiological method Ten µl of the patients plasma applied on a paper disc was put on Bacto Antibiotic Medium 5 (Difco) and the growth inhibiting capacity of *Sarcina Lutea* was determined The method has earlier been described in detail (1 7)

After the initial diagnostic measures the six infants where coeliac disease was suspected were prescribed a gluten free diet Repeated determination of the absorption of orally administered pc V was done in these six children after 2–3 months on diet After 6–8 months they were once again admitted for clinical examination and repeated small bowel biopsy was performed to check the histological improvement of the mucosa A test meal was given also at this occasion and the absorption of pc V was determined

RESULTS

In Fig 1 are shown the plasma concentrations of pc-V after the administration of 20 mg/kg b w of calcium pc V suspension to 1) Control patients which were children prescribed pc V because of upper respiratory tract infections 2) Children with suspected coeliac disease before diet and 3) infants admitted be

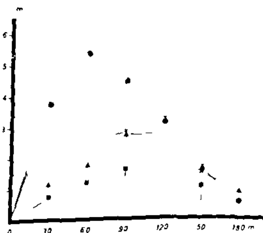

Fig 2 Plasma concentration (mean ±S E M) of penicillin after oral administration of 20 mg/kg b w of calcium pc V (Pencals®) in oil suspension Comparison between control children (12–24 months) ●—● (n=6) and patients with suspected coeliac disease (n=6) before diet ■—■ after 2 months of diet ▲—▲ and after 6–8 months of diet ×—×

one patient who had been on a gluten containing diet for the shortest time This patient (GA) showed only slight villous atrophy

In the test meal the absorption of *d* xylose is known to be relatively delayed and not to reach the same level as when an isolated *d* xylose absorption test is performed (10 12 14) Therefore if the plasma concentration reached 20 mg/100 ml or higher within three hours it was regarded as normal With this definition the *d* xylose absorption was pathologic in four of the six cases The vitamin A absorption was found to be normal in two cases in spite of villous atrophy Thus there was no definite correlation between the morphological findings of the small bowel biopsy and the absorption of either vitamin A *d* xylose or pc V at the initial investigation period

We could see an improvement of the histological appearance of the small intestinal mucosa after 6–8 months on a strict gluten free diet although three out of the six patients did not have a definite normalization which is known to take a longer time in some patients (17) At the same time we could see an improvement of the absorption of *d* xylose in most children There was also a definite improvement of the absorption of pc V even if it was still pathologic according to our criteria in two cases (HR and RLN) Thus the improvement of the absorptive ability seems to parallel the healing of the mucosa

The variability in the results of the absorption test especially initially at the time when the diagnosis was to be set further stresses the importance to rely more upon clinical signs and history than to the result of an absorption test in deciding whether or not to perform a small bowel biopsy in cases of suspected coeliac disease (9)

The patients in our study with suspected coeliac disease have later been challenged with a gluten containing diet and they will be followed to see if they will fulfil the criteria for coeliac disease (11) The results of this study will be reported separately

DISCUSSION

The uptake of pc V in healthy adults has been shown to take place predominantly in the proximal jejunum (5) For this reason it was plausible to believe that disorders affecting the proximal jejunum as e g coeliac disease should be associated with impaired absorption of pc-V

In this study we have shown that infants with suspected coeliac disease have a significantly impaired gastrointestinal absorption of pc V compared to a control group of infants treated for respiratory tract infection At the same time we have shown that infants with *long lasting diarrhoea but where the suspicion* of malabsorption could be ruled out did not significantly differ in the pc V absorption ability from a control group The results are in agreement with those obtained in adults where Davis & Pirola (3) found that three patients with gluten induced enteropathy verified by intestinal biopsy absorbed pc V definitely less than did normal subjects and patients with steatorrhea due to other reasons than gluten sensitivity

Parsons et al (15) studied the absorption of several drugs including pivampicillin ampicillin amoxycillin and cephalexin in adult patients with coeliac disease They concluded that the absorption of drugs in patients with coeliac disease could either be increased impaired delayed or unchanged No pattern according to physico chemical properties of the drugs could be seen in the change in the absorption of the different drugs However the study by Parsons et al (15) cannot be compared with ours since they investigated adult patients on a gluten free diet and intestinal biopsy was never performed during the study

The patients in this study have not yet fulfilled the diagnostic criteria for coeliac disease (see e g 11) which are as follows 1) clinical symptoms and histological changes of the small intestinal mucosa 2) clinical and histological improvement on a gluten free diet 3) histological and clinical relapse when gluten is reintroduced in the diet Therefore we have chosen to give our patients the diagnosis of suspected coeliac disease After introduction of a gluten free diet all patients showed normal weight gain and the gastrointestinal symptoms totally disappeared except in one case (HR) This patient showed evidence of having in addition a cow s milk protein intolerance and became clinically healthy when also cow milk was excluded from the diet

On the first admission our patients showed subtotal to moderate villous atrophy except in

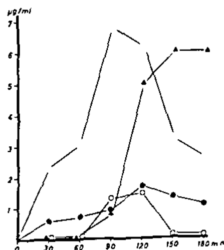

Fig 3 Plasma concentration of pencillin after oral administration of 20 mg/kg and 40 mg/kg b w of calcium pc V (Penicals®) in two patients with suspected coeliac disease before diet treatment HR 20 mg/kg b w O—O 40 mg/kg b w ×—× JS 20 mg/kg b w ●—● 40 mg/kg b w ▲—▲

GENETIC ENVIRONMENTAL INTERACTIONS IN PHYSICAL GROWTH

REYNALDO MARTORELL CHARLES YARBROUGH AARON LECHTIG
HERNAN DELGADO and ROBERT E KLEIN

From the Division of Human Development Institute of Nutrition of Central America and Panama (INCAP) Guatemala Guatemala C A

ABSTRACT Martorell R Yarbrough C Lechtig A Delgado H and Klein R E (Division of Human Development Institute of Nutrition of Central America and Panama (INCAP) Guatemala C A) Genetic environmental interactions in physical growth Acta Paediatr Scand 66 579 1977 —Variability in stature among young children is often ascribed to health and nutrition differences in malnourished populations and to genetic differences in well nourished populations Hence it was hypothesized that parent–child correlations in malnourished Guatemalan populations would be markedly lower than those reported for European samples Instead it was found that parent–child and sibling correlations were similar in both kinds of populations The simplest interpretation of these results is that variability in stature among malnourished children is as much a reflection of genetic differ ences as in developed nations However explanations can also be advanced which would attribute the higher than expected correlations to the environment For instance it could be that socioeconomic and nutritional status is correlated across generations In other words parents who had relatively better conditions as children are more likely to provide a better environment for their children Consequently the relative contribution of genetics and envi ronment to variability in height is still unsettled Nonetheless it appears that variability in body size in malnourished populations regardless of the relative importance of its causes is a useful indicator of health and nutrition

KEY WORDS Growth genetics height preschool children

Public health officials working with malnour ished children of developing nations generally assume that variability in height principally reflects differential nutrition and health his tories (7) This belief is derived from numer ous studies indicating that chronic malnutri tion (4) and high morbidity rates (13) cause physical growth retardation

On the other hand the corresponding as sumption in industrialized nations is that vari ability in height is to a large extent a reflec tion of differences in growth potentials (19) This assumption results from large bodies of data yielding genetically predictable relation ships between parental and child stature (10)

The variables one would like to correlate in growth genetic studies are the growth poten tials of parents and children In the developed nations environmental conditions may permit full expression of the genetic potential for sta ture On the other hand in chronically mal nourished populations height of both parents and children are not full expressions of the growth potential (5) Hence stature should be a poor proxy of genetic potential in mal nourished populations and parent–child stat ure correlations would be expected to be much lower in chronically malnourished populations than in well to-do nations

This paper describes parent–child and sib ling correlations in height in data collected in four Guatemalan villages Correlations at ages from 0 5 to 7 years are presented Since chro nic protein calorie malnutrition is endemic in

as to parenthood was obtained from the civil records which are believed to be highly reliable All information was collected between January 1969 and July 1975

The sample included 1 115 children for whom anthropometric data were available for one or more points in time and for one or both of the parents This represents 78% of the total population at risk Means and standard deviations of height from birth to 7 years of age for this sector which have been reported elsewhere (23) show rural Guatemalan children of both sexes to be substantially shorter than a well nourished reference sample from Denver Colorado (6) At birth differences are minor but later on increase until two years of age During the period comprised from ? to 5 years these differences are rather stable but then increase up to the age of 7 years when Guatemalan children are 13 cm shorter than those from Denver

The number of fathers mothers and parent pairs (i e both of them measured) as well as their mean height are given in Table 1 The percentage of fathers and mothers measured were 58% and 66% respectively In comparison to ?1 year old males from Denver (6) the fathers in our study are 19 cm shorter while the corresponding statistic for mothers is 17 cm Assortative mating for height is negligible for this population as the father–mother height correlation is 0 09 (n=260 N S) This value is lower than that of 0 3 usually reported for European populations (18 19)

For comparative purposes this paper utilizes data from samples of European descent The basic assumption is that these are healthy well nourished populations Two samples from the United States of America are included one from the longitudinal study of the Fels Research Institute in Ohio (? 3) and one from the Berkeley longitudinal study (1) The European samples include a combined sample of the London Brussels Stockholm and Zurich longitudinal studies (19) and a sample from the Finnish longitudinal study (?0) While these studies on populations of European descent do not constitute the total carried out up to date all of them are of a longitudinal character where children were carefully measured at specific ages and which included measured rather than reported parental heights

RESULTS

Table 2 shows parent–child correlations for height for ages 0 5 through 7 years Father–daughter correlations appear to be the lowest with no apparent differences between father–son mother–son and mother–daughter correlations Livson et al (10) have emphasized the fact that mother–child correlations are generally higher than father–child correlations The present findings are therefore only partially in agreement with the above observation As Tiisala & Kantero (20) point out highly conflicting observations have been reported in the literature on the relative effect of paternal and maternal height on the height of sons and daughters

Correlations between mid parent heights and heights of their children are presented in Table 3 for the study sample for USA samples (1 2) and for European samples (19 20) In all of these studies mid parent height was the average of the mother s and the father s height

The differences seen between the correlations in the four studies on populations of European descent (see Table 3) exemplify the range of values reported in the literature for such populations a point emphasized by Livson et al (10) who demonstrated that even pooled estimates of such parent–child correlations have wide confidence intervals at all ages

The correlations for the Guatemalan sample clearly do not differ from those of the European samples in the case of the mid parent–son correlations

There is some tendency for the Guatemalan mid parent–daughter correlations to be lower than those of the European samples In all cases correlations from the Fels (2) and the combined European sample (19) are higher than the mid parent–daughter correlations from the Guatemalan study Correlation from

these populations the hypothesis to be tested is that the correlations obtained in this study will be substantially smaller than those obtained in well nourished populations of European descent

METHODS

The data presented are drawn from an ongoing longitudinal study investigating the effects of chronic malnutrition on mental development and physical growth (9) Four rural ladino communities of Guatemala are being studied These villages are very poor their annual income per family being around $200 (USA) protein calorie malnutrition is endemic and morbidity rates are high

In the study described herein two variables were utilized total body length in children (which will be referred to as height) and standing height in parents Both were measured following standard techniques (22) and adequate measures of quality control (14) Children were examined within ±7 days of the required age Information

these populations the hypothesis to be tested is that the correlations obtained in this study will be substantially smaller than those obtained in well nourished populations of European descent

METHODS

The data presented are drawn from an ongoing longitudinal study investigating the effects of chronic malnutrition on mental development and physical growth (9) Four rural ladino communities of Guatemala are being studied These villages are very poor their annual income per family being around $[illegible]00 (USA) protein calorie malnutrition is endemic and morbidity rates are high

In the study described herein two variables were utilized total body length in children (which will be referred to as height) and standing height in parents Both were measured following standard techniques (22) and adequate measures of quality control (14) Children were examined within ±7 days of the required age Information

as to parenthood was obtained from the civil records which are believed to be highly reliable All information was collected between January 1969 and July 1975

The sample included 1 115 children for whom anthropometric data were available for one or more points in time and for one or both of the parents This represents 78% of the total population at risk Means and standard deviations of height from birth to 7 years of age for this sector which have been reported elsewhere (23) show rural Guatemalan children of both sexes to be substantially shorter than a well nourished reference sample from Denver Colorado (6) At birth differences are minor but later on increase until two years of age During the period comprised from 2 to 5 years these differences are rather stable but then increase up to the age of 7 years when Guatemalan children are 13 cm shorter than those from Denver

The number of fathers mothers and parent pairs (i e both of them measured) as well as their mean height are given in Table 1 The percentage of fathers and mothers measured were 58% and 66% respectively In comparison to 21 year old males from Denver (6) the fathers in our study are 19 cm shorter while the corresponding statistic for mothers is 17 cm Assortative mating for height is negligible for this population as the father–mother height correlation is 0 09 (n=260 N S) This value is lower than that of 0 3 usually reported for European populations (18 19)

For comparative purposes this paper utilizes data from samples of European descent The basic assumption is that these are healthy well nourished populations Two samples from the United States of America are included one from the longitudinal study of the Fels Research Institute in Ohio (2 3) and one from the Berkeley longitudinal study (1) The European samples include a combined sample of the London Brussels Stockholm and Zurich longitudinal studies (19) and a sample from the Finnish longitudinal study (20) While these studies on populations of European descent do not constitute the total carried out up to date all of them are of a longitudinal character where children were carefully measured at specific ages and which included measured rather than reported parental heights

RESULTS

Table 2 shows parent–child correlations for height for ages 0 5 through 7 years Father–daughter correlations appear to be the lowest with no apparent differences between father–son mother–son and mother–daughter correlations Livson et al (10) have emphasized the fact that mother–child correlations are generally higher than father–child correlations The present findings are therefore only partially in agreement with the above observation As Tiisala & Kantero (20) point out highly conflicting observations have been reported in the literature on the relative effect of paternal and maternal height on the height of sons and daughters

Correlations between mid parent heights and heights of their children are presented in Table 3 for the study sample for USA samples (1 2) and for European samples (19 20) In all of these studies mid parent height was the average of the mother s and the father s height

The differences seen between the correlations in the four studies on populations of European descent (see Table 3) exemplify the range of values reported in the literature for such populations a point emphasized by Livson et al (10) who demonstrated that even pooled estimates of such parent–child correlations have wide confidence intervals at all ages

The correlations for the Guatemalan sample clearly do not differ from those of the European samples in the case of the mid parent–son correlations

There is some tendency for the Guatemalan mid parent–daughter correlations to be lower than those of the European samples In all cases correlations from the Fels (2) and the combined European sample (19) are higher than the mid parent–daughter correlations from the Guatemalan study Correlation from

Unfortunately parent–child correlations were not reported in this study

As explained earlier in the introduction on the bases of purely statistical considerations it was expected that parent–child correlations obtained in our study would be substantially smaller in comparison to similar statistics found in studies of European samples As we have seen this is not the case How can this be so? We would like to offer two possible explanations It could be that the magnitude and severity of the environmental insults which the parents suffered as children are positively correlated with those which now plague their own children In other words parents with relatively better nutrition and health are likely to provide a relatively better environment for their children This is suggested by the fact that an index of the family s socioeconomic status a six point scale which summarizes construction materials size and cleanliness of the dwelling (8) is correlated with mid parental height ($r=0\ 3$) in the same magnitude to which it is correlated with the heights of children ($r=0\ 3$) However the partials of parental height on children s heights after controlling for socioeconomic status are not appreciably lower (i e 0 03 to 0 05 less) than the correlations already shown in Tables 3 and 4 Nonetheless the findings are highly suggestive that this explanation partially accounts for the higher than expected correlations observed

An alternative explanation can also be advanced All families of the villages which formed part of the study would be considered poor by most standards The within village variabilities in income health and nutrition are not as large as those to be found in urban settings in developing nations Thus it may be that the variability in environmental conditions is too narrow to noticeably lower the correlations In other words growth is less than maximal in these communities but the extent of growth retardation is more or less constant across individuals In a correlation analysis this would be equivalent to subtracting a constant from both variables the end result being that the original correlation would remain unchanged We have no way of testing this hypothesis within the design of our longitudinal studies

PUBLIC HEALTH IMPLICATIONS

Turning now to the public health use of physical growth as an indicator of nutritional and health status the findings presented are such that one still cannot claim to know how much of the variability in height in malnourished populations is reflective of nutritional and health events In well nourished populations relationships of the same magnitude as those found in our study have served as the basis for proposing parent size specific standards (3 19) Should the use of such standards be proposed for chronically malnourished populations as well? We think that they should not

The use of parent size specific standards would no doubt yield the conclusion that most children in communities similar to the ones studied by us are growing as expected and hence are normal This could be dangerously misleading in that normal for such a setting may be well below optimum Variability in body size among children is related to a series of risks such as morbidity and mortality (16) and to outcomes such as poor mental development Therefore it seems that variability in body size regardless of the relative importance of its causes is a useful public health measure until and unless body size can definitely be ruled out as an indicator of risk Nevertheless the question as to what standards should be used deserves careful consideration More studies such as the one presented here are needed before firm conclusions are reached

Garn & Rohmann (3)

the Berkeley (1) and the Finnish study (20) are higher than the Guatemalan mid parent–daughter correlations in all but two and one instances respectively

Sibling height correlation data are shown in Table 4 for the USA sample (3) and the Guatemalan population studied There appear to be no differences between these two sets of correlations The siblings correlations are higher than the parent–child correlation in the Guatemalan and the USA sample (3) This is not a surprising finding since siblings share a common home environment

DISCUSSION

The results presented in this paper have two types of broad implications The first has to do with current thinking on the nature–nurture debate while the second is concerned with the public health implications of the data We would like to comment on both of these concerns

Nature–nurture debate

Mueller (15) has recently reviewed the literature on parent–child correlation among *school age children* from a variety of genetic and environmental backgrounds He divided the studies into samples of European and non European descent and concluded that father–daughter and mother–daughter correlations for European samples were significantly greater but that this was not the case for father–son and mother–son The absolute differences however do not appear to be very large Moreover because the non European sample is over 50% Japanese and 8 to 9% American Black it is difficult to evaluate the role of chronic malnutrition in this comparison The same author (15) observed that in six samples roughly classified as malnourished height at 7 years of age was positively correlated with father–son and mother–daughter correlations However if the same analyses are carried out for father–daughter and mother–son correlations no relationship is observed

Data on parent–child correlations for pre school children from chronically malnourished populations are scant Some information has been provided for New Guinean populations (11 12 21) but the correlations reported in these studies are difficult to interpret because children of various ages are pooled in the analyses For instance groupings of children 1 to 4 years of age are utilized The statistical noise produced by variability in age would tend therefore to lower the parent–child correlations Pollit & Ricciuti (17) have shown that mothers and fathers of short children are shorter than the parents of relatively taller ones The sample was drawn from children attending day care centers whose working mothers lived in the slums of

Unfortunately parent–child correlations were not reported in this study

As explained earlier in the introduction on the bases of purely statistical considerations it was expected that parent–child correlations obtained in our study would be substantially smaller in comparison to similar statistics found in studies of European samples As we have seen this is not the case How can this be so? We would like to offer two possible explanations It could be that the magnitude and severity of the environmental insults which the parents suffered as children are positively correlated with those which now plague their own children In other words parents with relatively better nutrition and health are likely to provide a relatively better environment for their children This is suggested by the fact that an index of the family s socioeconomic status a six point scale which summarizes construction materials size and cleanliness of the dwelling (8) is correlated with mid parental height (r=0 3) in the same magnitude to which it is correlated with the heights of children (r=0 3) However the partials of parental height on children s heights after controlling for socioeconomic status are not appreciably lower (i e 0 03 to 0 05 less) than the correlations already shown in Tables 3 and 4 Nonetheless the findings are highly suggestive that this explanation partially accounts for the higher than expected correlations observed

An alternative explanation can also be advanced All families of the villages which formed part of the study would be considered poor by most standards The within village variabilities in income health and nutrition are not as large as those to be found in urban settings in developing nations Thus it may be that the variability in environmental conditions is too narrow to noticeably lower the correlations In other words growth is less than maximal in these communities but the extent of growth retardation is more or less constant across individuals In a correlation analysis this would be equivalent to subtracting a constant from both variables the end result being that the original correlation would remain unchanged We have no way of testing this hypothesis within the design of our longitudinal studies

PUBLIC HEALTH IMPLICATIONS

Turning now to the public health use of physical growth as an indicator of nutritional and health status the findings presented are such that one still cannot claim to know how much of the variability in height in malnourished populations is reflective of nutritional and health events In well nourished populations relationships of the same magnitude as those found in our study have served as the basis for proposing parent size specific standards (3 19) Should the use of such standards be proposed for chronically malnourished populations as well? We think that they should not

The use of parent size specific standards would no doubt yield the conclusion that most children in communities similar to the ones studied by us are growing as expected and hence are normal This could be dangerously misleading in that normal for such a setting may be well below optimum Variability in body size among children is related to a series of risks such as morbidity and mortality (16) and to outcomes such as poor mental development Therefore it seems that variability in body size regardless of the relative importance of its causes is a useful public health measure until and unless body size can definitely be ruled out as an indicator of risk Nevertheless the question as to what standards should be used deserves careful consideration More studies such as the one presented here are needed before firm conclusions are reached

* Garn & Rohmann (3)

the Berkeley (1) and the Finnish study (20) are higher than the Guatemalan mid parent–daughter correlations in all but two and one instances respectively

Sibling height correlation data are shown in Table 4 for the USA sample (3) and the Guatemalan population studied There appear to be no differences between these two sets of correlations The siblings correlations are higher than the parent–child correlation in the Guatemalan and the USA sample (3) This is not a surprising finding since siblings share a common home environment

DISCUSSION

The results presented in this paper have two types of broad implications The first has to do with current thinking on the nature–nurture debate while the second is concerned with the public health implications of the data We would like to comment on both of these concerns

Nature–nurture debate

Mueller (15) has recently reviewed the literature on parent–child correlation among *school age children* from a variety of genetic and environmental backgrounds He divided the studies into samples of European and non European descent and concluded that father–daughter and mother–daughter correlations for European samples were significantly greater but that this was not the case for father–son and mother–son The absolute differences however do not appear to be very large Moreover because the non European sample is over 50% Japanese and 8 to 9% American Black it is difficult to evaluate the role of *chronic malnutrition in this comparison* The same author (15) observed that in six samples roughly classified as malnourished height at 7 years of age was positively correlated with father–son and mother–daughter correlations However if the same analyses are carried out for father–daughter and mother–son correlations no relationship is observed

Data on parent–child correlations for pre school children from chronically malnourished populations are scant Some information has been provided for New Guinean populations (11 12 21) but the correlations reported in these studies are difficult to interpret because children of various ages are pooled in the analyses For instance groupings of children 1 to 4 years of age are utilized The statistical noise produced by variability in age would tend therefore to lower the parent–child correlations *Pollit & Ricciuti* (17) have shown that mothers and fathers of short children are shorter than the parents of relatively taller ones The sample was drawn from children attending day care centers whose working mothers lived in the slums of Lima Peru

THE EFFECTIVENESS OF PHENOBARBITAL IN THE PREVENTION OF RECURRENT FEBRILE CONVULSIONS IN CHILDREN WITH AND WITHOUT A HISTORY OF PRE PERI AND POSTNATAL ABNORMALITIES

SHELDON MARK WOLF

From the Department of Neurology Southern California Permanente Medical Group Los Angeles California USA

ABSTRACT Wolf Sheldon M (Department of Neurology Southern California Permanente Medical Group Los Angeles California USA) The effectiveness of phenobarbital in the prevention of recurrent febrile convulsions in children with and without a history of pre peri and postnatal abnormalities Acta Paediatr Scand 66 585 1977.—Three hundred children who had an initial febrile convulsion were divided into two groups In one group were children with a single brief generalized initial febrile seizure and no history of pre- peri or postnatal abnormalities which might suggest the possibility of brain damage and in the other group those with such abnormalities and/or a severe initial febrile convulsion Daily phenobarbital produced a significant decrease in febrile seizure recurrences in both groups as compared to children who received phenobarbital at the onset of fever and no phenobarbital prophylaxis Intermittent phenobarbital given at the onset of fever did not produce a significant difference in recurrence rate as compared with no phenobarbital

KEY WORDS Febrile convulsions phenobarbital

Ouellette in an excellent review of febrile convulsions (FC) in children (6) noted the difficulty in analyzing the prognosis and treatment effect in various series of children with FC because of variations in the proportion of normal children with short generalized seizures in different reports Only Livingston (4 5) she stated had separately presented the date concerning normal children

The purpose of the present study was to evaluate the effects of daily phenobarbital intermittent phenobarbital and no phenobarbital prophylaxis in two groups of children In one group were children with a single brief generalized initial febrile seizure and no history of pre peri or postnatal abnormalities which might suggest the possibility of brain damage and in the other group those with such abnormalities and/or a severe initial febrile convulsion

475

PATIENTS AND METHODS

Three hundred and fifty five children with an initial FC seen at the Kaiser Foundation Hospitals in Southern California from 1970 to 1975 were randomized into three groups according to the last digit of the chart number If this was 1–3 (Group I) continuous phenobarbital 3–4 mgm/kgm daily was prescribed with an additional load of 30 mgm/year up to a maximum of 120 mgm at the onset of fever followed by an increase in the dosage to 5 mgm/kgm for the duration of fever If the last digit was 4–6 (Group II) phenobarbital 5 mgm/kgm was prescribed to be given at the onset and for the duration of fever as well as an initial load of 30 mgm/year to a maximum of 120 mgm If the last digit was 7–9 (Group III) no phenobarbital prophylaxis was given If the last digit was 0 the preceding digit was used Fever was defined as a temperature over 100°F The parents of all children in the study were instructed about the importance of quickly lowering the temperature with aspirin (60 mgm/year) and cool water soaks They were also asked to bring the child promptly to the emergency area with any fever so that bacterial infection if present could be treated with antibiotics Subsequent visits were scheduled at 4–6 month intervals Details of compliance and monitoring of blood barbiturate levels are reported elsewhere (10)

36	12 4	32 1	<0 005

2 Birth weight under 5 lb
3 Prematurity
4 Difficult or complicated vaginal delivery or emergency caesarean section
5 Resuscitation
6 Abnormalities during the neonatal period (as jaundice cyanosis poor suck or cry respiratory difficulty)
7 Delay of developmental milestones
8 Severe head trauma
9 Behavior disorder prior to the initial FC
10 Initial febrile seizure lateralized or longer than 10 min
11 More than one seizure with initial febrile episode
12 Todd s phenomenon
13 Abnormal neurological examination

In the other group none of these criteria were present

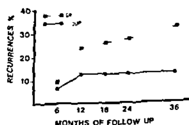

Fig 2 Recurrent FC in children with abnormal history

RESULTS AND CONCLUSION

Of 300 children who could be classified using the above criteria 85 (28%) were in the normal group and 215 (72%) were in the abnormal group In the normal group there were 31 children in Group I 31 children in Group II and 23 in Group III In the abnormal cohort there were 61 in Group I 87 in Group II and 67 in Group III

There were no significant differences in FC recurrence rates between Groups II and III in either the normal or abnormal categories (Tables 1 2) These were combined into one group for further analysis which we call Group II+III

There was a significant difference in recurrence rate between Group I and Group II+III in both categories (Tables 3 4 and Figs 1 2) The difference in recurrence rates in both the normal and abnormal groups was also statistically significant when Group I was compared with Groups II and III separately

These results confirm the studies of others that continuous phenobarbital is effective in preventing recurrent febrile convulsions (2 7 9)

For the sake of brevity the two groups will subsequently be called normal and abnormal without meaning to imply that any of the criteria listed below proved that any child actually had brain damage

The abnormal group included children with any one of the following

1 Pregnancy complicated by maternal infection bleeding hypertension toxemia or drug intake (other than vitamins)

Table 1 *Febrile convulsion recurrences in children with normal history*

2 Birth weight under 5 lb
3 Prematurity
4 Difficult or complicated vaginal delivery or emergency caesarean section
5 Resuscitation
6 Abnormalities during the neonatal period (as jaundice cyanosis poor suck or cry respiratory difficulty)
7 Delay of developmental milestones
8 Severe head trauma
9 Behavior disorder prior to the initial FC
10 Initial febrile seizure lateralized or longer than 10 min
11 More than one seizure with initial febrile episode
12 Todd s phenomenon
13 Abnormal neurological examination

In the other group none of these criteria were present

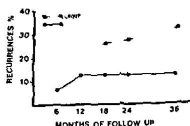

Fig 2 Recurrent FC in children with abnormal history

RESULTS AND CONCLUSION

Of 300 children who could be classified using the above criteria 85 (28%) were in the normal group and 215 (72%) were in the abnormal group In the normal group there were 31 children in Group I 31 children in Group II and 23 in Group III In the abnormal cohort there were 61 in Group I 87 in Group II and 67 in Group III

There were no significant differences in FC recurrence rates between Groups II and III in either the normal or abnormal categories (Tables 1 2) These were combined into one group for further analysis which we call Group II+III

There was a significant difference in recurrence rate between Group I and Group II+III in both categories (Tables 3 4 and Figs 1 2) The difference in recurrence rates in both the normal and abnormal groups was also statistically significant when Group I was compared with Groups II and III separately

These results confirm the studies of others that continuous phenobarbital is effective in preventing recurrent febrile convulsions (2 7 9)

ACKNOWLEDGEMENTS

This work was based on a cooperative multicenter study done in the Kaiser Foundation Hospitals in Los Angeles The physicians who participated in the study were Drs A Carr D Davis S Davidson E Dale E Goldenberg R Hanson G Lulejian M Nelson P Treitman and A Weinstein Computing assistance was obtained from the Health Sciences Computing Facility UCLA supported by NIH Special Research Resources Grant RR 3 We wish to thank Dr Alan Forsythe and Ms Ellen Sommers for their expert assistance in data analysis The work was supported by grants from the Epilepsy Foundation of America and the Southern California Permanente Medical Group

or intracranial infection were excluded Continuous phenobarbital was routinely tapered in Group I children at 5½ to 6 years

Life table methodology (1 3) was used to adjust for the different lengths of inclusion in the study The frequency of first febrile seizure recurrences was calculated for all children in the three treatment groups for various intervals following the initial FC The duration of follow up ranged from 6 to 70 months with a mean of 28 months in all groups

For the sake of brevity the two groups will subsequently be called normal and abnormal without meaning to imply that any of the criteria listed below proved that any child actually had brain damage

SHORT COLON MALFORMATION WITH IMPERFORATE ANUS

AJMER SINGH RAVINDER SINGH and AMARJIT SINGH

From the Department of Surgery and Paediatric Surgery Govt Medical College and Rajindra Hospital Patiala Pb India

ABSTRACT Ajmer Singh Ravinder Singh and Amarjit Singh (Department of Surgery and Paediatric Surgery Govt Medical College and Rajindra Hospital Patiala Pb India) Acta Paediatr Scand 66 589 1977.—Ten cases of a rare high anorectal malformation associated with short colon are presented The significance of a large gas fluid level (occupying more than half of the abdominal cavity on invertogram) is stressed for pre-operative diagnosis Terminal colostomy or ileostomy with disconnection of colo-vesical/colo-vaginal fistula has been considered the only adequate therapy Associated congenital malformations have been responsible for high mortality in these patients

KEY WORDS Short colon colovesical colovaginal colocloacal fistula

Imperforate anus is one of the very common congenital malformations It has a reported incidence of 1 5000 (6) Most of the infants born with this malformation can by and large be categorised by the classification of Stephens & Smith (6) and managed accordingly Associated congenital malformations of various organs are common These render the problem more complex and the management more difficult Association of imperforate anus of high type with a short colon and more often than not a colovesical or colovaginal fistula has been only occasionally reported in the literature This report relates to a series of ten cases encountered at the Rajindra Hospital Patiala Punjab India and a brief review of the available literature The details of these cases are given in Table 1

ILLUSTRATIVE CASE REPORTS

Case 6

K K 84705 a 1-day-old male weighing 700 g was admitted with imperforate anus and history of pneumaturia Plain radiograms in the inverted position vealed a single massive fluid level and air under the abdominal wall indicating pneumoperitoneum (Figs 3*a* and 3*b*) A provisional diagnosis of imperforate anus with short colon colovesical fistula and intestinal performation was made Laparotomy done on the same day revealed free gas in the peritoneal cavity perforation of the caecum absent large gut and a huge distended colonic pouch occupying the entire left half of the abdominal cavity The perforation was closed and a window colostomy performed A biopsy of the colonic wall revealed normal ganglionic pattern Disconnection of the colovesical fistula was not attempted at this stage The child had a good post-operative recovery Intravenous pyelogram done in the postoperative period was normal A cystourethrogram revealed a mild ureteric reflux A contrast study of the colonic pouch performed after introducing a catheter through the colostomy revealed the distended colonic segment and the wide colovesical fistula (Fig 4)

Case 7

K K 91172 a ?-day-old boy weighing ? 500 g was admitted with imperforate anus Invertogram revealed a high type of malformation with a typical large fluid level Laparotomy revealed malrotation of the intestine a massively distended colonic pouch and a colovesical fistula A window colostomy was performed without disconnecting the fistula The child made a quick and uneventful recovery Postoperative cystourethrogram revealed gross ureteric reflux hydroureter and hydronephrosis A contrast study of the colonic pouch done through the colostomy revealed the rudimentary colon and outlined the colovesical fistula (Fig 5)

At a second operation performed 3 weeks after the

SHORT COLON MALFORMATION WITH IMPERFORATE ANUS

2	3 day	M	High	–	Colostomy	Died
3	1 day	M	High	–	Colostomy	Died 8th day
4	5 day	F	High	–	–	Refused treatment
5	1 day	M	High	Congenital heart disease talipes equino varus	Colostomy	Died 3rd day
6	1 day	M	High colovesical fistula	Perforation of caecum hydro ureter & hydro nephrosis	Colostomy	Survived
7	2 day	M	High colovesical fistula	Malrotation of gut hydroureter and hydronephrosis	Colostomy and closure of fistula	Survived
8	2 day	M	High fistula?	Malrotation of gut	Colostomy	Died 6th day
9	7 mth	M	High colovesical fistula	Malrotation of gut	Colostomy closure fistula abdomino-perineal pull through	Survived now 6 yrs old
10	20 day	F	High colocloacal fistula	Double uterus malrotation of gut Meckel s diverticulum and absent appendix	Colostomy and closure of fistula	Died 18th day

first the colovesical fistula was disconnected The child recovered well and was sent home with a well functioning colostomy and is under follow up

Case 9

N S 97354 a 6 year old boy was first seen at 7 months of age with a history of repeated obstruction of colostomy The child had been born with apparently a high type of anal imperforation for which an unsuccessful perineal exploration and a caecostomy had been done elsewhere Laparotomy at that time revealed a short colon and malrotation of the intestine The caecostomy was refashioned at this stage At a subsequent operation done at 13 months of age a colovesical fistula was disconnected and an abdominoperineal pull through done The child recovered well

At 6 years of age the child now has considerable abdominal distension with complete fecal incontinence Barium meal and enema series (Fig 6 *a*) revealed a massively distended colonic pouch occupying more than the left half of abdomen

A cystourethrogram (Fig 6 *b*) demonstrated gross displacement of the urinary bladder to the right side

Case 10

B G 95667 a 20-day old female weighing 3 000 g was admitted with congenital absence of anus and history of passage of stools per vaginam Examination revealed a female configuration of external genitalia with a single opening through which the baby was passing both urine and stools The anus was absent at the normal site Plain invertograms showed a large fluid level Contrast studies through the perineal opening revealed a large intra abdominal cavity A clinical diagnosis of cloaca with short colon and colo-cloacal fistula was made Exploration of the abdomen revealed a large colonic pouch communicating below with the upper and posterior part of the cloaca which in turn was communicating further inferiorly but on its anterior surface with the urinary bladder There was a double uterus opening into the cloaca from either side A Meckel s diverticulum and intestinal malrotation were also present The colo-cloacal fistula was disconnected and a window colostomy done A biopsy of the colon sent for histological examination revealed normal ganglion cells The patient had an exceptionally good postoperative recovery but died after aspirating a feed on the eighteenth postoperative day Autopsy confirmed the operative findings There was no associated anomaly

OBSERVATIONS

In this series eight infants were males and two were females All had the high supralevator type of anorectal malformation Nine of these cases were operated upon In all of them on opening the abdomen the terminal ileum was found to enter a thin massively distended co

lonic pouch All attempts to deliver this pouch outside the wound for a loop colostomy failed and invariably a side or window colostomy had to be performed except in one case in which a catheter drainage of the sac was done

Associated malformations were very com mon in the cases included in this series Malro tation of the intestine was seen in four hydroureter and hydronephrosis in two dou ble uterus with a cloacal outlet in one and congenital heart disease in another case In case 6 there was perforation of the caecum with free air in the peritoneal cavity

Five of the operated cases (Nos 1 2 3 5 and 8) died within a few days In these cases a colovesical or colovaginal fistula could not be demonstrated However the invertograms of the first case clearly revealed a colovesical fistula by the presence of gas in the uri nary bladder In the remaining four cases detailed investigations such as colograms cystourethrograms excretory pyelograms barium studies colonic biopsies and re exploration of the abdomen were carried out In all these cases there was either a patent colovesical or a colocloacal fistula The fistu lous communication was always found to be very wide with easy and free flow of the con trast from the colonic pouch to the urinary bladder Another interesting finding was that the fistula opened into the bladder high up on its posterior surface below the fundus This is

Closure fistula colostomy	Died

in contrast to the usual finding in high anorec tal malformations where the *hind gut* com municates with the bladder just above the *in* ternal meatus

Another observation worth considering was that the terminal ileum opened into the short colonic pouch inferiorly very close to the site of the fistula This low entry of the ileum into the colonic pouch renders proper mobilisation of the colon for a definite pull through proce dure impossible In two cases biopsies taken from the colon wall showed normal ganglionic cells In the last case the superior mesenteric artery and its branches were found to supply the colonic pouch while the inferior mesen teric artery was missing

DISCUSSION

Trusler et al in 1959 (7) were probably the first to report in a series of seven cases the oc currence of short colon malformation in as sociation with imperforate anus They re viewed the literature and referred to a similar report by Spriggs (5) of a museum specimen consisting of imperforate anus and absent left colon Similar case reports have been made by Dickinson (2) Blunt & Rich (1) Singh & Pa thak (4) and Shafie (3) making a total of seven teen cases so far reported in the literature These cases are reviewed in Table 2

Although anorectal malformations are one of the commonest anomalies of the newborn (1 5000) it is very strange that so far only 11 cases have been reported having an associated short colon malformation from outside India Singh & Pathak (4) in 1972 reported six cases from Chandigarh India It is interesting to note that Chandigarh is only 70 kilometers from Patiala and both these places contain similar Punjabi populations How is it that this malformation is so common in this region? In our hospital short colon was encountered in roughly 4 38% of all cases of anorectal malformations and constituted approximately 10% of all cases with high malformation

We first became aware of this malformation in 1970 when the senior author operated upon case 9 The reports of Trusler et al (7) and Singh & Pathak (4) reinforced our awareness Since then a correct preoperative diagnosis has been possible in all the cases We agree with Singh & Pathak (4) that the most characteristic feature of short colon malforma tion which permits a correct preoperative diagnosis is the large fluid level obtained on an invertogram occupying nearly half and often more than half the abdominal cavity (Figs 1 2*a* and 2*b*)

On exploration of the cases one finds a thin congested distended sac representing the co lon The delivery of this sac for a loop co lostomy is impossible In our opinion the oc currence of a colovesical or a colovaginal fistula is more or less a standard feature of

short colon It was present in six of the seven cases reported by Trusler (7) and in all cases reported by Singh & Pathak (4) It was encountered in five of our more thoroughly investigated cases Pneumaturia in an infant indicates the presence of a colovesical fistula Invertograms may show gas in the bladder and often may also outline the gas filled fistula (Fig 2*a*) We have already emphasised the unusually large calibre of the fistula and its high opening into the bladder in our cases

Although male preponderance (8 2) is very striking in our cases as well as in the Singh & Pathak (4) series (5 1) it was not observed in other reports Short colon was associated with high anorectal malformation in 26 out of 27 cases so far reported The atypical case of Shafie (3) had short colon associated with perineal ectopic anus A high incidence of associated congenital malformations of other systems such as the gastrointestinal genitourinary cardiovascular etc has been mentioned in all reports

As regards management we disagree with the suggestion of Trusler (7) of an abdominoperineal pull through in short colon malformation We feel that this would fail because of a low entry of the terminal ileum into the colonic pouch and tailoring of the distended colon does not result in a proper evacuation of the colon We recommend a terminal colostomy after excision of the redundant colon or a terminal ileostomy as the most desirable procedure after disconnection of the fistula

ECHOCARDIOGRAPHIC ASSESSMENT OF LEFT VENTRICULAR FUNCTION DURING THE INJECTION OF ADRIAMYCIN

G BJÖRKHEM and S GARWICZ

From the Department of Paediatrics University Hospital Lund Sweden

ABSTRACT Bjorkhem G and Garwicz S (Department of Paediatrics University Hospital Lund Sweden) Echocardiographic assessment of left ventricular function during the injection of adriamycin Acta Paediatr Scand 66 595 1977 —Echocardiography was used to evaluate left ventricular function in 8 children treated with adriamycin for malignant disease Preejection period (PEP) left ventricular ejection time (LVET) and percent change in left ventricular internal dimension with systole (ΔLVID) were measured before during and immediately after 22 injections of adriamycin as well as 14 injections of other cytotoxic drugs and physiologic saline No immediate effects on left ventricular function could be discerned When functional parameters were evaluated longitudinally in patients with relatively higher cumulative doses of adriamycin percent change in left ventricular internal dimension with systole showed some tendency to decrease while the other parameters remained essentially unchanged

KEY WORDS Echocardiography adriamycin cardiotoxicity

Antibiotics of the anthracycline group particularly adriamycin have been shown to possess a significant activity against several malignancies and are therefore widely used (1) It appeared quite early that some patients treated with these drugs developed unexplained and often refractory heart failure Subsequent reports established the fact that the incidence of cardiomyopathy increased at higher cumulative doses of adriamycin and that a total dose of up to 500 mg/m² body surface is safe in terms of cardiac toxicity (4 8) However this may not be valid in patients who have received irradiation to the thorax which appears to potentiate the cardiotoxicity of adriamycin (3 4) The possibility of interaction with other drugs in this respect cannot be excluded either Moreover a recent study (11) showed that left ventricular function is impaired already after adriamycin in doses of 310–540 mg/m² Transient decrease in function occurred even in patients whose cumulative dose was less than 200 mg/m when these were studied 2 weeks after therapy by 4 weeks after therapy the left ventricular function returned to normal (11) Because the distribution of adriamycin after intravenous injection shows a rapid uptake in cardiac tissue (16) it seemed of interest to investigate left ventricular function during and immediately after the administration of the drug As a most appropriate method of studying this function echocardiography was chosen as reported below

PATIENTS AND METHODS

Eight children receiving adriamycin (Adriablastina Farmitalia) for the treatment of acute myeloblastic leukaemia (4 patients) acute lymphoblastic leukaemia in relapse (? patients) osteogenic sarcoma (1 patient) and leukaemic phase of lymphoblastic lymphoma (1 patient) were studied All of them were in good general condition and none showed signs of heart disease judged by history physical examination electrocardiography (ECG) and

short colon It was present in six of the seven cases reported by Trusler (7) and in all cases reported by Singh & Pathak (4) It was encountered in five of our more thoroughly investigated cases Pneumaturia in an infant indicates the presence of a colovesical fistula Invertograms may show gas in the bladder and often may also outline the gas filled fistula (Fig 2*a*) We have already emphasised the unusually large calibre of the fistula and its high opening into the bladder in our cases

Although male preponderance (8 2) is very striking in our cases as well as in the Singh & Pathak (4) series (5 1) it was not observed in other reports Short colon was associated with high anorectal malformation in 26 out of 27 cases so far reported The atypical case of Shafie (3) had short colon associated with perineal ectopic anus A high incidence of associated congenital malformations of other systems such as the gastrointestinal genitourinary, cardiovascular etc has been mentioned in all reports

As regards management we disagree with the suggestion of Trusler (7) of an abdominoperineal pull through in short colon malformation We feel that this would fail because of a low entry of the terminal ileum into the colonic pouch and tailoring of the distended colon does not result in a proper evacuation of the colon We recommend a terminal colostomy after excision of the redundant colon or a terminal ileostomy as the most desirable procedure after disconnection of the fistula

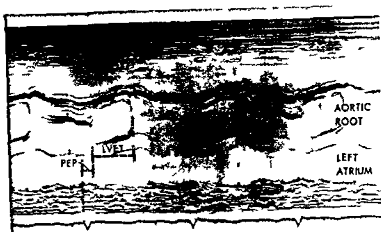

Fig 1 Echocardiogram of the aortic root showing PEP and LVET measurements

90 and 110% (unpublished material) PEP/LVET is claimed not to be influenced by heart rate or age and normal mean value is 0 313±0 05 (S D) (13)

Left ventricular internal dimensions were measured close to the tip of the anterior mitral leaflet where clear echoes from the endocardium and the left side of the septum could be obtained (Fig 2) The end-diastolic left ventricular internal dimension ($LVID_d$) was measured at the beginning of the QRS-complex and the end systolic left ventricular internal dimension ($LVID_s$) as the shortest distance between the septum and the endocardium in end systole ΔLVID was then calculated as

$$\frac{LVID_d - LVID_s}{LVID_d}$$

$LVID_d$ and $LVID_s$ were calculated as the mean of several consecutive beats and ΔLVID was compared to the normal mean value 36±4% (S D) given by Gutgesell et al (5) It was often not possible to obtain clear echoes for measuring PEP LVET and ΔLVID at each registration but when five or more measurements could be made at appropriate intervals during and after the injection a curve for each parameter was constructed to show the changes with time

RESULTS

The curves reflecting the changes with time for LVET % PEP/LVET and ΔLVID before during and after the injection of adriamycin were quite conformant showing only moderate variations and usually within the normal limits for the parameter (Fig 3) No certain

[a] Value obtained at the beginning of the injection
[b] Value obtained after the injection

chest X ray All patients were previously treated with other cytotoxic agents (Table 1) Adriamycin was used alone in doses of 30–40 mg/m² in patients A B and C in a dose of 20 mg/m² in combination with vincristine in patients D E G and H and in the same dose in combination with cytosine arabinoside in patient F Thirty six echocardiographic recordings were obtained during 22 injections of adriamycin 8 injections of vincristine 2 injections of cytosine arabinoside 1 injection of cyclophosphamide and 3 injections of physiologic saline Adriamycin was given as a rapid intravenous injection during 1 to 2 minutes after dilution in sterile water to a concentration of 2 mg/ml

The echocardiograms were recorded with an Echocardiovisor ultrasonoscope (Organon Technica) with a fiber optic recorder using a 4 5 MHz unfocused transducer Examinations of the aortic leaflets and the left ventricle were made before the injection was started during the injection and then at about one minute intervals during the following ten minutes The transducer was held in standard positions (2) and care was taken to obtain the same position for registering the left ventricle each time During a few examinations a constant transducer position was ensured by registering only the left ventricle during and after the injection The degree of variation in left ventricular internal dimension in this situation was comparable to that found when the position of the transducer was changed between left ventricle and aortic root Registrations from the aortic leaflets were made using a paper speed of 100 mm/sec and from the left ventricle with a paper speed of 50 or 100 mm/sec

From the echocardiograms left ventricular preejection period (PEP) left ventricular ejection time (LVET) and left ventricular internal dimensions in end diastole and end systole ($LVID_d$ $LVID_s$) were measured PEP was measured from the beginning of the QRS complex to the opening of the aortic leaflets and LVET from the opening to the closing of the aortic leaflets (Fig 1)

LVET was corrected for heart rate using the regression equation of Spitaels et al (13) and expressed as LVET percent of normal (LVET %) From PEP and LVET the quotient PEP/LVET was also calculated In left ventricular dysfunction LVET % decreases and PEP/LVET increases (15) Excluding the newborn period LVET is not influenced by age and can be corrected for heart rate to LVET % (6 13) The normal range lies between

tracing and phonocardiogram (15) but especially in children echocardiography is an easier way of obtaining these parameters and an excellent correlation between values measured from echoes and from carotid pulse tracings has been shown (7)

In several studies PEP/LVET and ΔLVID have been shown to be the most sensitive measures of left ventricular dysfunction (5 14) and therefore these parameters were chosen in this study also including LVET % as another parameter independent of heart rate and age

Rinehart et al have recently shown that chronic adriamycin induced cardiac injury can be detected from systolic time intervals before clinical signs appear (11) Since adriamycin reaches high levels in cardiac muscle very rapidly after an intravenous injection (16) and transient ECG changes sometimes can be seen (4 8) this study was undertaken to study the immediate effects of adriamycin on left ventricular function No significant alteration in left ventricular function could be found as judged by PEP/LVET LVET % and ΔLVID during and immediately after the injection of adriamycin With the cumulative doses of adriamycin reached in this study the functional parameters also remained essentially stable The two patients A and B who received the highest cumulative doses showed only a slight decrease in ΔLVID These findings are difficult to evaluate yet but have to be followed up with further longitudinal studies

Patient C differs from the rest of the group His left ventricular function was impaired before the first injection of adriamycin and actually improved during treatment We have no ready explanation to this but it is possible that he had primary myocardial engagement of the malignant disease that improved with treatment

In conclusion no immediate negative effect of adriamycin on left ventricular function could be shown but a careful follow up of patients receiving this drug is necessary Echocardiography makes it possible to study left ventricular function regularly in these patients detect early changes and alter treatment accordingly

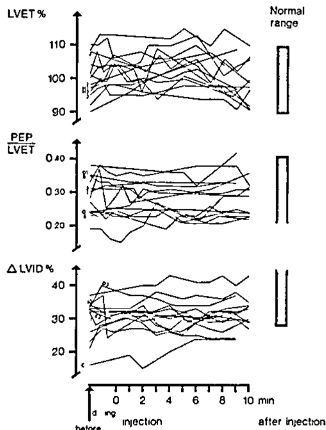

Fig 3 Parameters of left ventricular function (LVET PEP/LVET ΔLVID) before during and after the injection of adriamycin Normal range for each parameter is indicated Letters and numbers signify patients and investigation no as used in Table 1

trend for the variations could be discerned The same was found when other cytotoxic agents as vincristine cyclophosphamide and cytosine arabinoside were injected and also during the injection of physiologic saline Fig 4 shows the similarities of the curves when adriamycin vincristine and physiologic saline were injected in the same patient Left ventricular function was also followed longitudinally by comparing functional parameters at the beginning of each examination (Table 1) Patient A and B reached a cumulative dose of adriamycin of 300 and 450 mg/m² respectively during the study period and showed a slight decrease in ΔLVID during the same period but so far normal LVET % and PEP/LVET Patient C showed clearly pathological values before the start of this investigation and without previous treatment with adriamycin His initial ΔLVID was 16% and PEP/LVET 0 48 Left ventricular function improved in this patient during treatment with adriamycin reaching normal values for PEP/LVET and improving but still abnormal ΔLVID

DISCUSSION

Echocardiography offers an excellent tool in heart investigation in both adults and children (2 9) The method is direct yet non invasive and can be used to assess left ventricular function both from left ventricular contractility (5 10 12) and from systolic time intervals (7) Systolic time intervals have earlier mostly been derived from ECG indirect carotid pulse

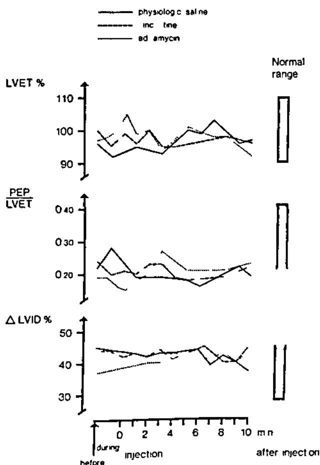

Fig 4 Parameters of left ventricular function (LVET PEP/LVET ΔLVID) before during and after consecutive injections of vincristine physiologic saline and adriamycin in the same patient

STUDIES ON MATURITY IN NEWBORN INFANTS

IX *Further Observations on the Use of External Characteristics in Estimating Gestational Age*

ORVAR FINNSTRÖM

From the Department of Paediatrics University Hospital Linkoping Sweden

ABSTRACT Finnstrom O (Department of Paediatrics University Hospital Linkoping Sweden) Studies on maturity in newborn infants IX Further observations on the use of external characteristics in estimating gestational age Acta Paediatr Scand 66 601 1977 — A simple method for assessing maturity based on 8 external characteristics has previously been described Some new results with the use of this method are now presented The precision in estimating gestational age is sufficiently good more than 95% of the infants were correctly estimated within ±3 weeks Reducing the criteria to seven and thereby excluding the ophthalmoscopic examination did not significantly change the precision of the estimation The examination based on external characteristics is a very simple and useful method for maturity assessment even in sick newborn infants Tables for transforming maturity score into gestational age are presented

KEY WORDS Maturity gestational age newborn infants external characteristics

In a series of earlier papers the author discussed and compared several methods for assessing maturity in newborn infants (2 7–13) In these studies the scoring of external characteristics was recommended as the method of choice for routine work (11 12 13) The method has been used with highly satisfactorily results in the routine clinical work in our Department In the original description 8 external characteristics were included The use of pupillary membranes necessitating an ophthalmoscopic examination has been of some concern to several clinicians however We therefore thought it could be of value to assess the method comparing the estimation of gestational age using either 8 or 7 criteria i e excluding the eye examination We also want to give some more information regarding the accuracy in determining gestational age by this method and discuss the problem of maturity assessment in the light of the recent literature The examination technique will be presented in some detail again and also simple tables for transforming maturity score into gestational age

MATERIAL

Criteria for selection

Only infants for whom reliable information about gestational age was available were included in the study The criteria have been given in detail previously (7)

Definitions and abbreviations used

Gestational age age in days from the first day of the mother s last menstrual period until the day of birth ***40th week*** days 274 to 280 ***SGA*** small for gestational age Infant with birth weight below −2 S D in the relation between birth weight and gestational age according to Swedish standard curves ***AGA*** appropriate for gestational age Infant with birth weight within normal limits for the gestational age (between −2 and +2 S D) ***LGA*** large for gestational age Infant with birth weight above +2 S D according to Swedish standard curves ***Preterm*** gestational age less than 267 days postmenstrual ***Term*** gestational age between 267 and 294 days ***Postterm*** gestational age more than 294 days postmenstrual ***Maturity*** as used by the authors maturity is an expression of the degree of development of the newborn infant Maturity thus defined is dependent on the gestational age of the infant but also on other factors such as biological variation ***LMP*** last menstrual period

Table 1 *Transforming maturity score to gestational age (days)*

26	295		

Investigated material

Details of this material have been given in an earlier paper (12) The distribution in different gestational age groups was as follows Below 225 days (5 infants) 225–238 (10) 239–252 (13) 253–266 (29) 267–280 (35) above 280 (33) Total number of infants 125 Only 2 infants were SGA 2 were LGA

METHODS

The infants were examined on the first or second day of life by one examiner Eight criteria were examined and scored according to 2 to 4 alternative responses (scores) as follows

1 *Breast size* The transverse diameter is measured bi laterally with a sliding caliper and the largest value re gistered (*a*) below 5 mm (*b*) 5 to 10 mm (*c*) more than 10 mm

2 *Nipple formation* Estimated by inspection (*a*) nipple barely visible no areola (*b*) nipple well defined areola present but not raised (*c*) nipple well defined edge of the areola raised above the skin

3 *Skin opacity* Estimated by inspection of the trunk (*a*) numerous veins tributaries and venules are clearly seen particularly over the abdomen (*b*) veins and tri butaries are seen (*c*) a few large blood vessels are clearly seen over the abdomen (*d*) a few large blood vessels are seen indistinctly over the abdomen or no blood vessels are seen

4 *Scalp hair* The scalp hair is inspected (*a*) fine hair wooly or fuzzy individual strains difficult to dis tinguish (*b*) hair coarse and silky Each hair appears as a single strand

5 *Ear cartilage* The ears are palpated in order to estimate the distribution of ear cartilage In case there is a difference between the two ears the judgment is based on the most mature ear (*a*) no cartilage is felt in anti tragus (*b*) cartilage is felt in antitragus (*c*) cartilage is present in anthelix (*d*) cartilage formation is completed in helix (i e cartilage can be palpated in the dorsal cranial part)

6 *Finger nails* The finger nails are inspected and the finger tip palpated (let the nail scratch the hand of the examiner) (*a*) the nails do not reach the fingertips (*b*) the nails reach the fingertips (*c*) the nails reach or pass the finger tips distal edge of the nail is distinct and relatively firm (i e the edge of the nail can easily be felt if the nail scratches the hand of the examiner)

7 *Plantar skin creases* The sole of the foot is in spected Only the relatively broad creases are analysed Fine superficial lines may be present especially if the skin is dry but usually disappear if the sole is stretched from toes to heel (*a*) no skin creases are present (*b*) anterior transverse creases only are present (*c*) occasional creases are seen on the anterior two-thirds of the sole (*d*) the whole sole is covered with creases i e also the heel

8 *Pupillary membranes* The pupillary plane is examined after widening of the pupils with a short acting mydriatic agent with the aid of an ophthalmoscope (*a*) membrane rests are seen in the form of distinct arcades (*b*) one or several separate strands are seen uni or bi laterally (*c*) no membrane rests are seen over the widened pupil

Criteria number 2 and 3 are essentially as described by Farr et al (5) number 4 and 7 according to Usher et al (25) and number 5 6 and 8 essentially after von Harnack & Oster (15)

Gestational age can be calculated as follows The individual scores are summed this sum (total maturity score) is divided by the maximal maturity score possible for that infant (depending on how many criteria that are used) and estimated gestational age is calculated from the formula Y(days)=145 62+149 38 X(8) More simply the total maturity score for 8 or 7 criteria can be transformed to gestational age in days according to Table 1

RESULTS

The results of the calculations of gestational age from maturity scores are given in Table 2 in comparison with gestational ages based upon LMP Thus a correct estimation of gestational age within ±2 weeks was obtained in 88% of the cases 98% of the cases were correctly estimated within ±3 weeks There were practically no differences in the results using 7 or 8 criteria in calculating gestational age For short gestational ages there is a tendency to overestimate the gestational ages There was also a slight tendency to under estimate gestational age after post term de liveries

Table 2 *Number of infants correctly estimated within ±2 and 3 weeks respectively*

	Correct estimation within ±2 weeks (14 days)		Correct estimation within ±3 weeks (21 days)	
	8 criteria	7 criteria	8 criteria	7 criteria
All infants (*n*=125)	110 (88%)	109 (87 2%)	123 (98 4%)	122 (97 6%)
Gestational age <267 days (*n*=57)	49	48	57	56
Gestational age 267–294 days (*n*=59)	55	55	58	58
Gestational age >294 days (*n*=9)	6	6	8	8

DISCUSSION

The present investigation further support the practical value of this method based on external characteristics for maturity assessment in the newborn period The examination is sufficiently exact also at low gestational ages It is less suitable in differentiating between term and post term pregnancies Practically all infants were correctly estimated regarding age to within ±3 weeks which corresponds well with the theoretically estimated precision (11) The few cases in which the gestational age was miscalculated might well depend on incorrect figures for LMP given by the mother although these figures were carefully controlled Several other authors also showed the value of external characteristics in assessing gestational age (1 4 6 17 22 24)

Some previous authors claim that it is possible to estimate gestational age to within 1–2 weeks These statements were based on the calculated 95% confidence limits for estimating gestational age at mean values of the scores However as pointed out previously (11) general conclusions cannot be drawn from these confidence limits since they have been constructed from materials that differ very much regarding the distribution of gestational ages Meyer Dietrich (20) in a recent study on mainly pre term infants using the Farr (5) and Dubowitz (4) scoring system got considerably broader confidence limits as did Brueton et al in an earlier study (3) He also pointed out that differences in confidence limits depend more on differences in the composition of the materials than on differences in the work up of the studies or the quality of the tests used

In an earlier paper we said that the precision in estimating gestational age was less when the number of criteria was reduced from 8 to 7 in our method (8) From a practical point of view as showed in this paper this difference is too small to be of any importance Thus it is not necessary to use the ophthalmoscopic examination which some clinicians find difficult to perform

In a similar manner Nicolopoulos et al (21) recently showed that it is possible to reduce the number of criteria in the Farr score from 11 to 9 and the number of criteria in the neurological part of the Dubowitz score from 10 to 8 without losing precision in the estimation of gestational age

Parkin et al (23) who also used the Farr score even suggested that it would be possible to reduce the number of criteria in this examination to only 4 However at low values of the score a change in only one point of the total score leads to much greater changes in gestational age than at higher values of the score The method based on only four criteria seems to be rather inexact for low scores There is probably therefore an optimal number of items which should not be reduced (in our scoring this is 7 criteria)

Dubowitz et al (4) showed earlier that the precision in estimating gestational age was increased when a combination of external characteristics and neurological tests were used as did the present author (11) This finding has been confirmed by others (21) but has

Table 1 *Transforming maturity score to gestational age (days)*

Maturity score (8 criteria)	Gestational age (days)	Maturity score (7 criteria eyes excluded)	Gestational age (days)

Investigated material

Details of this material have been given in an earlier paper (12) The distribution in different gestational age groups was as follows Below 225 days (5 infants) 225–238 (10) 239–252 (13) 253–266 (29) 267–280 (35) above 280 (33) Total number of infants 125 Only 2 infants were SGA 2 were LGA

METHODS

The infants were examined on the first or second day of life by one examiner Eight criteria were examined and scored according to 2 to 4 alternative responses (scores) as follows

1 *Breast size* The transverse diameter is measured bilaterally with a sliding caliper and the largest value registered (*a*) below 5 mm (*b*) 5 to 10 mm (*c*) more than 10 mm

2 *Nipple formation* Estimated by inspection (*a*) nipple barely visible no areola (*b*) nipple well defined areola present but not raised (*c*) nipple well defined edge of the areola raised above the skin

3 *Skin opacity* Estimated by inspection of the trunk (*a*) numerous veins tributaries and venules are clearly seen particularly over the abdomen (*b*) veins and tributaries are seen (*c*) a few large blood vessels are clearly seen over the abdomen (*d*) a few large blood vessels are seen indistinctly over the abdomen or no blood vessels are seen

4 *Scalp hair* The scalp hair is inspected (*a*) fine hair wooly or fuzzy individual strains difficult to distinguish (*b*) hair coarse and silky Each hair appears as a single strand

5 *Ear cartilage* The ears are palpated in order to estimate the distribution of ear cartilage In case there is a difference between the two ears the judgment is based on the most mature ear (*a*) no cartilage is felt in antitragus (*b*) cartilage is felt in antitragus (*c*) cartilage is present in anthelix (*d*) cartilage formation is completed in helix (i e cartilage can be palpated in the dorsal cranial part)

6 *Finger nails* The finger nails are inspected and the finger tip palpated (let the nail scratch the hand of the examiner) (*a*) the nails do not reach the fingertips (*b*) the nails reach the fingertips (*c*) the nails reach or pass the finger tips distal edge of the nail is distinct and relatively firm (i e the edge of the nail can easily be felt if the nail scratches the hand of the examiner)

7 *Plantar skin creases* The sole of the foot is inspected Only the relatively broad creases are analysed Fine superficial lines may be present especially if the skin is dry but usually disappear if the sole is stretched from toes to heel (*a*) no skin creases are present (*b*) anterior transverse creases only are present (*c*) occasional creases are seen on the anterior two-thirds of the sole (*d*) the whole sole is covered with creases i e also the heel

8 *Pupillary membranes* The pupillary plane is examined after widening of the pupils with a short acting mydriatic agent with the aid of an ophthalmoscope (*a*) membrane rests are seen in the form of distinct arcades (*b*) one or several separate strands are seen uni or bilaterally (*c*) no membrane rests are seen over the widened pupil

Criteria number 2 and 3 are essentially as described by Farr et al (5) number 4 and 7 according to Usher et al (25) and number 5 6 and 8 essentially after von Harnack & Oster (15)

Gestational age can be calculated as follows The individual scores are summed this sum (total maturity score) is divided by the maximal maturity score possible for that infant (depending on how many criteria that are used) and estimated gestational age is calculated from the formula Y(days)=145 62+149 38 X(8) More simply the total maturity score for 8 or 7 criteria can be transformed to gestational age in days according to Table 1

RESULTS

The results of the calculations of gestational age from maturity scores are given in Table 2 in comparison with gestational ages based upon LMP Thus a correct estimation of gestational age within ±2 weeks was obtained in 88% of the cases 98% of the cases were correctly estimated within ±3 weeks There were practically no differences in the results using 7 or 8 criteria in calculating gestational age For short gestational ages there is a tendency to overestimate the gestational ages There was also a slight tendency to under estimate gestational age after post term deliveries

TREATMENT OF SEPTICAEMIA IN THE NEWBORN INFANT CHOICE OF INITIAL ANTIMICROBIAL DRUGS AND THE ROLE OF EXCHANGE TRANSFUSION[1]

U TOLLNER F POHLANDT F HEINZE and I HENRICHS

From the Department of Paediatrics Section of Neonatology University of Ulm/Donau Federal Republic of Germany

ABSTRACT Tollner U Pohlandt F Heinze F and Henrichs I (Department of Paediatrics Section of Neonatology University Hospital Ulm Federal Republic of Germany) Treatment of septicaemia in the newborn infant Choice of initial antimicrobial drugs and the role of exchange transfusion Acta Paediatr Scand 66 605 1977 —The therapeutic success of antibiotics used at the beginning of treatment and the effect of exchange transfusion in cases of septicaemia were tested in 22 newborn infants The clinical course of these patients was compared with the outcome of 11 newborn infants who received antibiotic treatment without exchange transfusion The following results were obtained 1) All 6 patients initially receiving antibiotics which were ineffective in vitro died In this group of patients the incidence of septic organ involvements (meningitis ventriculitis peritonitis) was significantly increased 2) Following exchange transfusion an impressive clinical improvement was consistently observed 3) In patients who had initially received effective antibiotics and exchange transfusion the lethality was significantly lower than in patients without exchange transfusion 4) Our bacteriological findings show that continuous monitoring of cultures from blood CSF and stool is necessary to choose the most effective antibiotic in the prevailing nosocomical circumstances

KEY WORDS Newborn infant septicaemia antibiotics exchange transfusion

Septicaemia of the newborn infant runs a rapid course and has a high lethality rate (9 15 23) It is accepted that its outcome is dependent on the efficacy of early antibiotic treatment although very few data are available to support this belief (5 17) Case reports dealing with successful use of exchange transfusion in septicaemia of the newborn infant (12 13) prompted us to apply this measure as ultima ratio in newborns with sepsis The unexpected improvement we observed led us to perform exchange transfusion earlier in the clinical course of rapidly deteriorating patients

[1] Presented in part at the 4th Symposium of Paediatric Intensive Care Medicine Mainz Oct 9–11 1975

The purpose of this paper is to demonstrate the effect of (*a*) initial choice of antibiotics and (*b*) exchange transfusion upon the lethality of neonatal septicaemia

PATIENTS AND METHODS

Patients

An exchange transfusion (e t) was performed as treatment for septicaemia [illegible]8 times in [illegible] newborns who were transferred to the intensive care unit from March 1974 to March 1975 The case histories of these patients were retrospectively analysed The data on gestational age birthweight and sex of the infants are shown in Fig 1 and Table 1 Prior to the onset of septicaemia 19 patients had developed respiratory distress syndrome Respiratory support was given by face mask CPAP in 16 infants and

been questioned by Shingwekar et al (24) and Meyer Dietrich (20) The Dubowitz scoring system has become very popular and its value has been proved in pre term infants (14 19) and in twins of dissimilar size (18) as well as in infants of African origin (3, 22) However misleadingly low scores might be found in infants born by extended breech delivery and in infants requiring prolonged resuscitation (14)

The increase in the precision in estimating gestational age by adding neurological tests to external characteristics is rather small if at all Therefore it is preferable to use only the external characteristics in routine work The external score is not influenced by the clinical state of the infants although small for gestational age infants are scored a little too low (5 11) The examination of external characteristics certainly upsets the sick infant much less than a neurological examination

Table 2 *Combinations of antimicrobial drugs which were used at the beginning of treatment for neonatal septicaemia during 1973–1975*

Combination of antibiotics No 1	
Gentamicin sulfate	5 mg/kg bodyweight during the first week of life given in 2 divided doses i m
	7 5 mg/kg bodyweight after the first week of life given in 3 divided doses i m
Oxacillin sodium	200 mg/kg bodyweight (max 300 mg/kg) given in 4 divided doses i v
Carbenicillin disodium	700 mg/kg bodyweight (max 1 000 mg/kg) given in 4 divided doses i v
Combination of antibiotics No 2	
Colistimethate sodium	16 mg/kg bodyweight given in 2 divided doses during the first week of life thereafter in 3 divided doses i m
Cephalothin sodium	60 mg/kg bodyweight given in 4 divided doses i v

after improvement during the first e t In 1? cases prednisolone was given 2 to 4 times at a dose of 5–10 mg per kg bodyweight to aid in control of septic shock (14 22 4 26 29) In 1973 3 patients received comparable doses of prednisolone

Statistical methods

The results were statistically validated by application of Fisher s exact test and the Mann Whitney rank sum test

RESULTS

Clinical outcome

From March 1974 to March 1975 22 newborns with severe septicaemia were treated of whom 11 survived (Fig 2)

Group 1 Five patients showed predominant cerebral lesions at autopsy which had caused death independently of septicaemia In one case an extensive haemorrhage into the falx cerebri subarachnoid space and both lateral ventricles was found In a second case wide spread pneumonia after aspiration of amniotic fluid and bilateral intraventricular haemorrhage were revealed Three further cases died of extensive cerebral haemorrhage

Table 3 *Organisms isolated from blood cultures of newborn infants Groups 2 and 3*

Figures within parentheses denote organisms resistant to initially used antibiotics

	1973 with out e t	1974/75 with e t
Escherichia coli	3	4
Enterobacter/klebsiella	3	11 (4)
Bacterium proteus	–	2 (1)
Pseudomonas aeruginosa	2	–
Enterococcus	–	1 (1)
β haemolytic Streptococcus Group A	–	1
Streptococcus viridans	–	1
Rods of coryneform group	1	–
Staphylococcus aureus	3	1

Group 2 Ten of 11 patients without localised involvements of septicaemia survived Gram negative bacteria were the causative organisms in 7 cases One patient died of sepsis due to enterococci resistant to the initially used antibiotics despite a second e t which was performed when he was moribund

Group 3 Five of 6 patients with localised involvements of sepsis died Four patients succumbed to meningitis and ventriculitis One patient who had received five e t on different days finally died and at autopsy was found to have intense purulent and fibrinous peritonitis forming a solid mass of the complete small intestine However the patient s condition improved during each e t and remained so for several hours afterwards

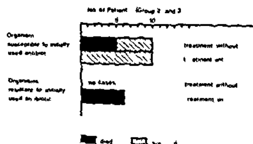

Fig 3 Result of treatment for neonatal septicaemia dependent on performance of exchange transfusion and susceptibility of isolated organisms (blood culture) to initially used antibiotics

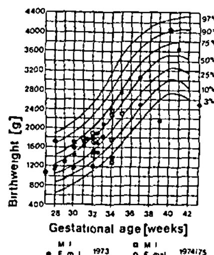

Fig 1 Newborn infants with septicaemia receiving different forms of treatment Distribution of birthweight gestational age and sex Local growth chart (21)

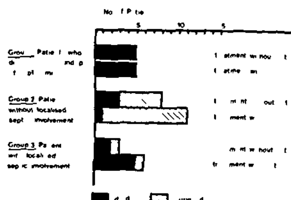

Fig 2 Effect of exchange transfusion on the outcome of neonatal septicaemia

by mechanical ventilation in 2 cases The patients were subdivided into three groups according to the following clinical symptoms and autopsy findings (Fig 2)

Group 1 Patients who died of nonseptic causes ($n=5$)

Group 2 Patients without localized septic involvement ($n=11$)

Group 3 Patients with localized septic involvement (meningitis ventriculitis peritonitis) ($n=6$)

The clinical course of patients who were treated with antibiotics and e t in 1974/75 was compared with the outcome of 16 newborns in 1973 who had received no e t (Fig 1 and Table 1) The patients with and without e t in both groups were comparable in regard to birthweight gestational age sex distribution history incidence of *respiratory distress syndrome course of illness change of* white cell count differential blood smear (27) antimicrobial treatment heparin and prednisolone dosage

Methods

The clinical diagnosis of septicaemia was made on the following grounds change of skin colour muscular hypotonia development of metabolic acidosis apneic spells and increased oxygen requirement Leukocytosis with a shift to the left and subsequent leukopenia supported the diagnosis A full discussion of the validity of these criteria has been reported previously (27)

Table 1 *Newborn infants with septicaemia*

	Median	Range
Birthweight (g)		
1973 (without e t)	1 740	1 150–3 650
1974/75 (with e t)	1 750	960–4 050
Gestational age (weeks)		
1973 (without e t)	32	28–43
1974/75 (with e t)	32	27–40
Sex distribution	Female	Male
1973 (without e t)	11	5
1974/75 (with e t)	12	10

After bloood samples cerebrospinal *fluid* stool and throat swabs had been obtained for bacteriological examination antibiotic therapy was started using arbitrarily either the combination of colistimethate sodium with cephalothin sodium or oxacillin sodium and carbenicillin disodium with gentamicin sulfate (Table 2)

To confirm the clinical diagnosis of septicaemia samples for culture were taken by venous and arterial puncture or from an umbilical venous catheter immediately after insertion (3) They were injected into brain heart infusion bottles (Mikrognost®)[1] and incubated at 37°C The susceptibility of the isolated bacteria was checked by a modified Kirby Bauer technique (4) using DST agar[2] against the following antibiotics (µg content of disc) oxacillin sodium (10) carbenicillin disodium (100) cephalothin sodium (30) colistimethate sodium (10) and gentamicin sulfate (10) As soon as the result was available—36 to 48 hours after initiation of treatment—the drug was changed if indicated All infants received about 100 U heparin/kg bodyweight per day which was added to the parenteral infusion Based on clinical considerations but not on coagulation studies heparin dosage was increased to 500 U in 6 arbitrarily chosen patients of the e t group and in 2 patients of the control group respectively in order to prevent consumption coagulopathy

E t was indicated whenever signs of septic shock developed A pale dirty skin colour accompanied by diminished microcirculation of skin and change from orange to greenish icterus served as predominant diagnostic criteria of septic shock aside from increasing oxygen requirement and metabolic acidosis (27) In 8 patients fresh heparinised blood in plastic bags was used containing 4 5 U heparin per ml The remaining 14 patients received ACD blood All infants received blood of their own blood group *The exchange transfusion was per*formed intermittently by 10 ml steps via umbilical vessel catheter The transfused volume amounted to about three times the blood volume of the patient but at most 450 ml Two patients received 2 and 5 e t respectively because signs of septic shock again developed some hours

ly improved humoral and cellular defense mechanisms We suppose that bacteria and endotoxins may be diluted and removed by e t Most recently reported animal experiments favour this hypothesis The survival rate of rabbits which had received endotoxin intravenously was significantly increased after an exchange transfusion (20) The removal of endotoxins might be followed by a diminished sensitivity of the peripheral vessels to catecholamines (14 29) Thus dilatation of these vessels improves the pale gray skin colour The spontaneous adjustment of metabolic acidosis and decreased oxygen requirement may also be a result of improved microcirculation It was striking that the clinical improvement which was well documented in some cases by arterial oxygen measurements began shortly after starting exchange transfusion However this response after 50–100 ml of exchange transfusion cannot be attributed exclusively to removal of endotoxins but might be produced by an endotoxin inhibitor in transfused blood Normal plasma is able to inhibit or detoxify endotoxin (16 25) A similar rapid increase of arterial oxygen pressure was most recently reported in premature infants with severe respiratory distress syndrome who had received exchange transfusion as a form of therapy (10) This response was thought to be a result of the removal of substances that might induce pulmonary hypoperfusion Heparin was not of significant value but could on the other hand not be shown to have increased the incidence of intracranial haemorrhage Prednisolone did not affect patient survival significantly Quite frequently neutropenia sometimes accompanied by the presence of immature granulocytes in the differential blood smear can be observed in neonatal septicaemia (27) Phagocytic capacity is attained at the myelocyte stage but is maximal at the polymorphonuclear stage (6) Transfusion of fresh blood might lead to an immediate increase of phagocytic capacity by both an enlargement of the granulocyte pool and by an increase of mature granulocytes

In addition there is evidence of humoral deficiency in the defence mechanisms of these infants Granulocytes of premature and term newborn infants have been shown to possess full phagocytic capacity when opsonization is intact (8 18) A deficiency of opsonization however has been proved against E coli Pseudomonas Staph aureus and Serratia marcescens in the serum of premature infants (8 18) A similar defect was shown against E coli and Serratia marcescens in the serum of term newborn infants (7) In addition the capacity of opsonization seems to correlate with the concentration of complement component C3 which again correlates with the age of gestation In newborn infants the amount of C3 and C5 in the serum is only about 50% of normal adult values (1)

IgM antibodies are needed for the activation of the complement system in the defence against Gram negative bacteria These antibodies are not available in newborn infants but the alternate pathway can be activated without antibodies It has been shown that in some newborn infants one component of this pathway is missing (2) Finally the serum of newborn infants seems to be devoid of a certain chemotactic factor (19) Transfusion of fresh blood might correct some or all of the factors causing the increased susceptibility of newborn infants to overwhelming infections

Experience concerning e t in the treatment of septicaemia in the newborn infant is not great Only short communications or case reports are available (12 13 28 30) This retrospective analysis may be less conclusive than a prospective controlled study but the data indicate that the therapeutic result in this life threatening illness is certainly improved by e t

Choice of antibiotics at the beginning of treatment

In 1974/75 6 of 17 patients with septicaemia without intracerebral haemorrhage (Groups 2 and 3) were initially treated with a combination of antibiotics which proved to be ineffective in vitro (Fig 3 and Table 3) All 6 patients died The lethality rate in this group of patients who had received ineffective antibiotics during the first 36 to 48 hours of treatment was significantly increased compared with the effectively treated patients ($p<0\ 001$) Four of the 6 deceased newborn infants developed meningitis or ventriculitis Localised involvement of septicaemia occurred more frequently whenever initial treatment was not effective ($p=0\ 005$) All infants who had not received e t were treated by effective antibiotics at the beginning of therapy (Fig 3) However in three cases local manifestations of sepsis developed

Exchange transfusion

The clinical improvement during e t was consistently impressive Normal skin colour returned sometimes after only 50 ml of blood had been exchanged The frequency of apneic spells decreased and the oxygen content of incubator atmosphere or respirator air could be lowered and still keep the infants well oxygenated At times spontaneous breathing began during e t The frequently observed muscular hypotonia improved and spontaneous movements were resumed The metabolic acidosis which was always an accompanying finding could be corrected more easily In some cases in which serial measurements of arterial oxygen pressure and pH were made this improvement was well documented

Patients of groups 2 and 3 who had been treated with e t in 1974/75 were compared with those in 1973 who fell into the same groups but did not receive e t (Fig 3) All newborn infants in whom e t had been performed survived The case fatality rate was significantly reduced in patients who had received e t ($p=0\ 018$) This reduced lethality still holds after excluding those three patients without positive blood culture in whom the diagnosis of septicaemia was made on clinical grounds only ($p=0\ 040$)

DISCUSSION

Newborns especially premature infants who suffer from septicaemia only respond to early treatment because the disease runs such a rapid course (14 23) The necessarily blind antibiotic treatment used initially is therefore *of major importance in achieving therapeutic* success All our patients who had initially received ineffective antibiotics died

In 1974/75 6 of 21 isolated organisms were found to be resistant to the initial blind treatment There was no difference in the efficacy of any of the antibiotic combinations *colistimethate/cephalothin and oxacillin/car*benicillin/gentamicin in vitro In retrospect the combination of colistimethate/gentamicin would have been indicated for all bacteria isolated during this period

Treatment should be initiated as soon as the diagnosis is suspected and before the microorganism has been identified taking into account the bacteria likely to be encountered in the particular environment Information available in the literature concerning the spectra of antimicrobial drugs must be considered with caution since the reported bacterial spectra and sensitivity testing differ from one hospital to another perhaps because the use of different antibiotics in different treatment centers However continuous monitoring of organisms isolated from blood cerebrospinal fluid and stool including antibiotic susceptibility testing makes possible judicious selection of drugs likely to be effective in the initial blind treatment against the local bacterial spectrum

The mode of action of e t in the treatment of septicaemia remains hypothetical The following possibilities may be considered firstly rapid control of circulatory shock and second

ly improved humoral and cellular defense mechanisms We suppose that bacteria and endotoxins may be diluted and removed by e t Most recently reported animal experiments favour this hypothesis The survival rate of rabbits which had received endotoxin intravenously was significantly increased after an exchange transfusion (20) The removal of endotoxins might be followed by a diminished sensitivity of the peripheral vessels to catecholamines (14 29) Thus dilatation of these vessels improves the pale gray skin colour The spontaneous adjustment of metabolic acidosis and decreased oxygen requirement may also be a result of improved microcirculation It was striking that the clinical improvement which was well documented in some cases by arterial oxygen measurements began shortly after starting exchange transfusion However this response after 50–100 ml of exchange transfusion cannot be attributed exclusively to removal of endotoxins but might be produced by an endotoxin inhibitor in transfused blood Normal plasma is able to inhibit or detoxify endotoxin (16 25) A similar rapid increase of arterial oxygen pressure was most recently reported in premature infants with severe respiratory distress syndrome who had received exchange transfusion as a form of therapy (10) This response was thought to be a result of the removal of substances that might induce pulmonary hypoperfusion Heparin was not of significant value but could on the other hand not be shown to have increased the incidence of intracranial haemorrhage Prednisolone did not affect patient survival significantly Quite frequently neutropenia sometimes accompanied by the presence of immature granulocytes in the differential blood smear can be observed in neonatal septicaemia (27) Phagocytic capacity is attained at the myelocyte stage but is maximal at the polymorphonuclear stage (6) Transfusion of fresh blood might lead to an immediate increase of phagocytic capacity by both an enlargement of the granulocyte pool and by an increase of mature granulocytes

In addition there is evidence of humoral deficiency in the defence mechanisms of these infants Granulocytes of premature and term newborn infants have been shown to possess full phagocytic capacity when opsonization is intact (8 18) A deficiency of opsonization however has been proved against E coli Pseudomonas Staph aureus and Serratia marcescens in the serum of premature infants (8 18) A similar defect was shown against E coli and Serratia marcescens in the serum of term newborn infants (7) In addition the capacity of opsonization seems to correlate with the concentration of complement component C3 which again correlates with the age of gestation In newborn infants the amount of C3 and C5 in the serum is only about 50% of normal adult values (1)

IgM antibodies are needed for the activation of the complement system in the defence against Gram negative bacteria These antibodies are not available in newborn infants but the alternate pathway can be activated without antibodies It has been shown that in some newborn infants one component of this pathway is missing (2) Finally the serum of newborn infants seems to be devoid of a certain chemotactic factor (19) Transfusion of fresh blood might correct some or all of the factors causing the increased susceptibility of newborn infants to overwhelming infections

Experience concerning e t in the treatment of septicaemia in the newborn infant is not great Only short *communications or case* reports are available (12 13 28 30) This retrospective analysis may be less conclusive than a prospective controlled study but the data indicate that the therapeutic result in this life threatening illness is certainly improved by e t

PAIN CRY IN FULL TERM ASPHYXIATED NEWBORN INFANTS CORRELATED WITH LATE FINDINGS

KATARINA MICHELSSON PERTTI SIRVIÖ and OLE WASZ HÖCKERT

From the II Department of Paediatrics and Department of Phonetics University of Helsinki Finland

ABSTRACT Michelsson K Sirvio P and Wasz Hockert O (II Department of Paediatrics and Department of Phonetics University of Helsinki Finland) Pain cry in full term asphyxiated newborn infants correlated with late findings Acta Paediatr Scand 66 611 1977.—115 pain induced cries from 45 full term newborn infants with pre and perinatal asphyxia were analyzed by sound spectrographic methods All the infants had signs of intrauterine asphyxia and Apgar score of 6 or less at 5 min The mean birth weight was 3 170 g The pain cries were recorded before the age of 8 days 83 % of the cries before 3 days of age The cry analysis was compared with the pain cries of 75 full term healthy newborn infants of corresponding birth weight and gestational age The results showed significant differences between the cries of the asphyxiated newborn and the healthy infants The duration of the phonation was shorter the maximum and minimum pitch of the fundamental frequency was significantly higher Bi phonation and vibrato occurred more often double harmonic break and glottal roll less often An increase in rising falling rising and flat types of melody was observed Retrospectively the cries were more abnormal if the infant was found to be neurologically damaged at the check up at 2–8 years

KEY WORDS Crying asphyxia newborn infant sound spectrography

Sound spectrographic methods have shown that the crying of healthy newborn infants has many specific features Different cry signals such as hunger and pain can be recognized both auditively and spectrographically (9 10 11) Since the beginning of the 1960s our study group has been analyzing the cry of both healthy neonates and those with different diseases and congenital abnormalities One part of our research programme was to study the cry characteristics of asphyxiated new born infants (4 5) with the purpose of discovering which characteristics of the pain cry correlate with the degree of asphyxia and the later findings for the child We have strong reasons to believe that cry analysis can be one more criterion in assessing not only the diagnosis but also the prognosis in the new born period

MATERIAL AND METHODS

The neonates The series comprised 45 newborn infants studied in 1966–71 at the Institute of Midwifery Hel sinki or in 1972–75 at the Children s Hospital Univer sity of Helsinki All the infants were full term with a gestational age of 38–42 weeks The mean birth weight was 3 170 g range 2 430–5 000 g

The infants were selected for the material according to two criteria signs of intrauterine asphyxia and the Apgar score at 5 min Changes in the foetal heart rate and dis colouring of the amniotic fluid were taken as signs of intrauterine asphyxia All the infants had an Apgar score at 5 min of 6 or less the score was 1–3 for 10 infants and 4–6 for 35 infants The score at one minute was 0–3 in 17 cases 4–6 in 27 cases and 7–10 in one case The Apgar scores at 15 min were 0–3 4–6 and 7–10 for 4 15 and 26 infants respectively

In the neonatal period many of the infants had neuro logical symptoms 6 had convulsions 3 cyanotic attacks 3 had signs of cerebral haemorrhage 6 of hypotonia 4 of rigidity and 2 of hyperirritability Two infants had tremor for several days Two of the infants had a slightly increased respiratory rate during the first day of life The blood sugar and the bilirubin were checked for all the

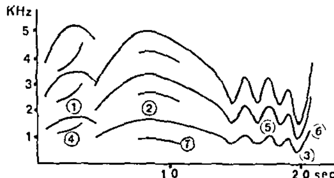

Fig 1 A schematic drawing of a sonagram displaying the following cry parameters 1 shift 2 maximum pitch 3 minimum pitch 4 bi phonation 5 vibrato 6 gliding and 7 double harmonic break

infants and showed no deviation from the normal limit at the time of the cry recordings

Controls The control series comprises 75 healthy full term newborn infants

Follow up At the check up examination at 2–8 years 11 of the children had marked neurological sequelae 5 had epileptic convulsions one of these was additionally severely mentally retarded Three more children had severe mental retardation and one of them had spastic hemiplegia as well Two children had moderate motor and mental retardation One child had developed hydrocephalus which was attributed to cerebral haemorrhage in the neonatal period Two of the infants had died in the newborn period with cerebral lesions according to the autopsy report

The mean birth weight of these two groups healthy and diseased was 3 150 g and 3 260 g respectively The Apgar scores were worse in those who had neurological sequelae later Of the 13 damaged infants 10 had Apgar scores below 6 at 1 5 and 15 min compared with 11 of the 32 children who were healthy at the time of the follow up

Recording of the cries The cries were tape recorded after a pinch on the upper arm or the ear thus called pain cry All the 115 signals were recorded before the age of 8 days Seventy were recorded during the first day of life all but 19 within 3 days of birth Forty five pain cries were analyzed from the 13 infants who had died or had neurological sequelae at check up and 70 from the 28 children who were healthy at the check up

Equipment and analyzing methods The pain induced cry signals were tape recorded on an Uher 4000 L tape recorder or a Sony TC 55 cassette tape recorder with an AKG 58 D 200 microphone

1–3 cries were analyzed from each infant usually the first phonation after the pinch The second and the third phonation of a few cries were also analyzed

The duration measurements were made with a mingograph (Elema Schonander Sweden) and the sound spectrographic analysis with a Sona Graph 6061 B (Kay Elemetrics Inc USA) The sound spectrograph provides a visualization of the cry signal a sonagram from which different cry parameters can be measured as shown schematically in Fig 1

A detailed explanation of the phonetic characteristics measured has been published by Wasz Hockert et al 1968 (9) and Michelsson 1971 (4) Therefore only a summary description is given here Fourteen cry attributes were measured The duration of the phonation the minimum and maximum pitch of the fundamental frequency the occurrence and maximum of shift We also noted the change in the melody type defined as falling rising falling rising falling-rising or flat In some of the cries no melody type was detectable A marked instability of the fundamental frequency was also noted as can be seen in Fig 2 We also observed the continuity and voicing of the signals and the glottal roll i e a low frequency voiced sound and the occurrence of the following parameters depicted on the schematic sonagram (Fig 1) bi phonation gliding vibrato and double harmonic break These characteristics were measured if the duration was at least 0 1 sec

RESULTS

The results of the analysis of the 115 cry signals of the 45 full term asphyxiated newborn infants are compared with the crying of 75 healthy full term newborn infants in Table 1 There were significant differences between the two series in the following cry characteristics

(*a*) The duration of the cry signals of the asphyxiated infants was significantly shorter

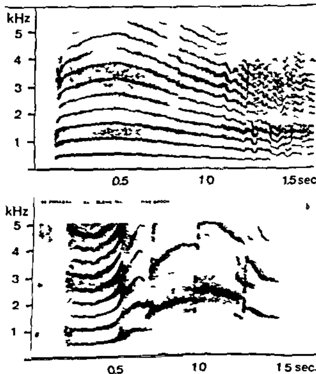

Fig 2 Pain cry of a healthy newborn infant (*a*) and of an infant with asphyxia at birth (*b*) The fundamental frequency of the cry in asphyxia is more high pitched and unstable

Table 1 *Results of the cry analysis of the 45 asphyxiated infants*
In separate columns the cry analysis with reference to later outcome

	Asphyxiated infants

Glottal roll %	20	27[b]	9	51

$^{a}p<0.05$ $^{b}p<0.01$ $^{c}p<0.001$ Significance levels refer to differences between the characteristics in asphyxiated infants and controls

(*b*) The maximum and minimum pitch of the fundamental frequency was increased No healthy infant had a cry with a maximum pitch of over 1 000 Hz while 40 of the 115 cries of the asphyxiated infants exceeded this level

(*c*) The melody type which is mainly falling or rising–falling in the crying of healthy infants showed a significant increase in rising falling–rising and flat types of melody in the asphyxiated group Occasionally no melody type could be measured e g when the signal was very unstable or when a rising–falling–rising or falling–rising–falling type of melody occurred

(*d*) A significant increase was also noted in the occurrence of bi phonation vibrato double harmonic break and glottal roll

(*e*) A slight but not statistically significant increase was observed in the continuity and voicing of signals in the asphyxiated infants Gliding not seen in the crying of healthy neonates occurred in a few signals of the asphyxiated infants

(*f*) No significant change was seen in the occurrence of the shift part However in healthy neonates the shift part when present occurred in 4/5 at the beginning of the signal while in the asphyxiated infants it was at the beginning of the signal in about 1/3 of the cries

Table 1 also shows the results of the cry analysis of the asphyxiated infants in different columns according to the later findings Many of those characteristics which in the asphyxiated infants changed from the normal crying were still more marked when the asphyxiated infant died or was later found to be damaged for instance the falling and rising–falling type of melody decreased from 63% to 53% the

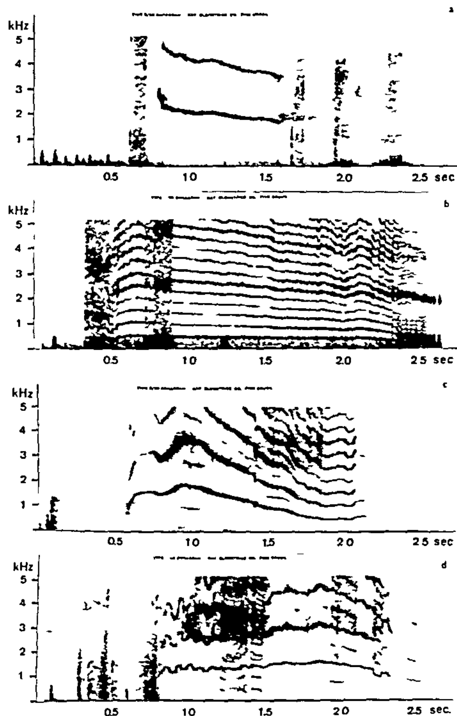

Fig 3 Pain cry signals recorded at the age of 1 day (*a* and *c*) and 8 days (*b* and *d*) The cries *a* and *b* are recorded from an infant healthy at follow up The cry was normal at 8 days The other infant developed CP and the cry at 8 days (*d*) was still very abnormal

occurrence of bi phonation increased from 30% to 40% the maximum pitch (Md) increased from 640 Hz to 1 000 Hz and the signals (Md) were much shorter 1 2 sec compared with 2 3 sec for healthy neonates

The table shows the significance levels matched to the normal series Comparison of the two groups of asphyxiated infants showed a statistically significant difference in the duration of the signals in the minimum and maximum pitch and in the occurrence of unstable signals and glottal roll

DISCUSSION

Sound spectrographic analysis of crying in infants has been studied systematically by our research group since the beginning of the 1960s when Wasz Hockert et al published their first analysis of different cry types such

as hunger pain and birth cries (11) Normative data for the crying of normal healthy infants were established in 1968 (9) Michelsson 1971 (4) showed that prematurely born infants cry differently from full term infants and that the differences were more marked the more premature the infant was For this reason we did not include premature babies in this study thus omitting differences in the cry characteristics due to prematurity

The criteria we selected for intrauterine asphyxia in this study were changes in the foetal heart rate and discolouring of the amniotic fluid We were aware of the problems of interpreting these symptoms but no better methods were available in 1966 when the first cries for this study were recorded The criterion for perinatal asphyxia was the Apgar score at 5 min since it has a better prognostic and diagnostic value than the one minute score (1)

The cry of infants with asphyxia has previously been studied by Michelsson (4) She showed that the crying of asphyxiated newborn infants had significant differences from that of healthy newborn infants These results concur with the findings of this work The purpose of this study was to ascertain whether the changes in some characteristics are more marked in newborn infants with severe asphyxia and whether more abnormal characteristics occur in those infants who were neurologically damaged at the follow up

Our study reveals that the crying of asphyxiated infants shows significant changes from the crying of healthy newborn infants The more high pitched cry found in infants with asphyxia is also audible to the ear In healthy neonates no cry exceeded 1000 Hz In the crying of the asphyxiated infants 35% of the cries exceeded this level If the child later was found to be damaged half of the cry signals had a pitch above 1000 Hz The minimum pitch was also significantly increased

In some of the phonations of the asphyxiated infants both the maximum and minimum pitch were well within the normal range but other abnormal characteristics occurred in these cries such as a change in the melody type or an occurrence of bi phonation or gliding We have attributed all these changes in the cry characteristics with a causal connection to the brain structure as they do not occur in the crying of infants with anomalies in the oral region such as cleft palate (6)

In the asphyxiated infants the shift part when present occurred more often at the middle or the end of the phonation a fact that has not attracted our attention hitherto The connection between the location of the shift part and the instability of the fundamental frequency is obvious and also the increase of vibrato can be connected with pitch instability The decrease in the occurrence of the low pitched glottal roll may be due to the overall shortening of the signals with a weaker and more abrupt termination of the cry

We observed in this study that the characteristics in the crying of asphyxiated infants which significantly differed from those of healthy infants were still more marked in those who were abnormal at check up Accordingly we feel that cry analysis can be one more expedient for diagnosing the possible brain damage resulting from severe asphyxia The measurements can be made more reliable by repeating the cry recordings This can be seen from Fig 3 which shows the cry characteristics of one infant who was normal at check up and those of another infant who had convulsions at the follow up In both cases the cries were recorded at 1 and 8 days of age It is noticeable how the cry becomes more normal as the child recovers but still has many abnormal qualities when the child is found to be damaged later

CELL MEDIATED IMMUNITY AND IMMUNOGLOBULIN LEVELS IN LIGHT FOR DATE INFANTS

C BHASKARAM N RAGHURAMULU and VINODINI REDDY

From the National Institute of Nutrition (Indian Council of Medical Research) Jamai Osmania Hyderabad India

ABSTRACT Bhaskaram C Raghuramulu N and Reddy V (National Institute of Nutrition Hyderabad India) Cell mediated immunity and immunoglobulin levels in light for-date infants Acta Paediatr Scand 66 617 1977.—Cell mediated immune response and circulating levels of immunoglobulins were studied in 75 full term newborn babies The results showed that though the immunoglobulin levels were not altered cell mediated immunity was significantly depressed in infants with birth weight less than 2 500 g and this may result in lowered resistance to infection

KEY WORDS Cell mediated immunity immunoglobulins light for date infants

It is now well established that both humoral as well as cell mediated immune mechanisms are impaired in children with severe protein calorie malnutrition rendering them more susceptible to infections as shown by Reddy & Srikantia (7) and Bhaskaram & Reddy (2) Results of more recent studies conducted by Reddy et al (8) however have indicated that in mild and moderate degrees of protein calorie malnutrition as judged by growth retardation the same severe impairment in immunological responses are not seen This observation may have relevance not only to postnatal malnutrition but also to intra uterine malnutrition Ghosh (4) reported an increased frequency of infections in infants with low birth weight In India the incidence of low birth weight babies weighing less than 2 500 g is as high as 30% and a majority of them are full term light for-date infants There is little information regarding the functional status of such infants The present study was undertaken to assess the immunocompetence of light for date babies

SUBJECTS AND METHODS

Seventy five full term newborn babies were studied Gestational age was determined by the date of last menstrual period of the mother and confirmed by physical and neurological maturity of the newborn as suggested by Lubchenco (5) Cord blood samples were collected and the following investigations done

CELL MEDIATED IMMUNITY AND IMMUNOGLOBULIN LEVELS IN LIGHT FOR DATE INFANTS

C BHASKARAM N RAGHURAMULU and VINODINI REDDY

From the National Institute of Nutrition (Indian Council of Medical Research) Jamai Osmania Hyderabad India

ABSTRACT Bhaskaram C Raghuramulu N and Reddy V (National Institute of Nutrition Hyderabad India) Cell mediated immunity and immunoglobulin levels in light for-date infants Acta Paediatr Scand 66 617 1977 —Cell mediated immune response and circulating levels of immunoglobulins were studied in 75 full term newborn babies The results showed that though the immunoglobulin levels were not altered cell mediated immunity was significantly depressed in infants with birth weight less than 2 500 g and this may result in lowered resistance to infection

KEY WORDS Cell mediated immunity immunoglobulins light for-date infants

It is now well established that both humoral as well as cell mediated immune mechanisms are impaired in children with severe protein calorie malnutrition rendering them more susceptible to infections as shown by Reddy & Srikantia (7) and Bhaskaram & Reddy (2) Results of more recent studies conducted by Reddy et al (8) however have indicated that in mild and moderate degrees of protein calorie malnutrition as judged by growth retardation the same severe impairment in immunological responses are not seen This observation may have relevance not only to postnatal malnutrition but also to intra uterine malnutrition Ghosh (4) reported an increased frequency of infections in infants with low birth weight In India the incidence of low birth weight babies weighing less than 2 500 g is as high as 30% and a majority of them are full term light for date infants There is little information regarding the functional status of such infants The present study was undertaken to assess the immunocompetence of light for-date babies

SUBJECTS AND METHODS

Seventy five full term newborn babies were studied Gestational age was determined by the date of last menstrual period of the mother and confirmed by physical and neurological maturity of the newborn as suggested by Lubchenco (5) Cord blood samples were collected and the following investigations done

Table 1 *Cell mediated immunity in newborn babies*

Group	Birth weight (g)	No of babies	Total lymphocyte count/mm³	Percentage of T cells	³H thymidine incorporation counts per min in test culture / counts per min in control culture
I	>2 500	6	3 44±740 9	56 8±1 43	24 4
II	? 250–? 500	10	3 876±9?9 0	5? 3±3 ?6	10 9
III	<? 250	13	3 144±648 0	36 7±3 01*	3 4*

Values are mean ±S E
$p<0.05$
* $p<0.01$ compared with Group I

Table 2 *Immunoglobulin levels in newborn babies*

Group	Birth weight (g)	No of babies	Immunoglobulins mg/100 ml IgG	IgM	IgA
I	>2 500	45	1 478 0±117 1	12 5±1 28	0 6±0 20
II	2 250–2 500	17	1 751 0±149 1	10 9±2 19	0 5±0 10
III	<2 250	13	1 563 0±173 45	9 9±1 50	1 0±0 59

Values are mean ±S E

Total lymphocyte count was obtained by making total and differential leukocyte counts The cell mediated immune response was assessed by T lymphocyte count as measured by rosette formation technique described by Wybran et al (9) and ^{3}H thymidine incorporation into lymphocyte cultures following PHA stimulation described in the method reported by Bhaskaram & Reddy (2) The results are expressed as the ratio of counts per minute in test culture and control culture

Serum IgG IgM and IgA were determined by radial immunodiffusion technique of Mancini (6)

RESULTS

The infants were divided into three groups based on the birth weight There were 45 infants weighing more than 2 500 g and 17 infants weighing between 2 250 and 2 500 g Thirteen infants weighed less than 2 250 g and only 3 of them were below 2 000 g

The mean level of the ratio of ^{3}H thymidine incorporation in the test to the control culture and percentage of T lymphocytes were 24 4 and 56 8 respectively in babies weighing more than 2 500 g Values for ^{3}H thymidine incorporation into lymphocytes of babies weighing less than 2 500 g were significantly lower The number of T cells however was significantly lower only in those weighing less than 2 250 g as compared with infants with birth weights above 2 500 g (as shown in Table 1) The total lymphocyte counts did not differ in the three groups of newborns

The concentration of IgG in cord blood was much higher than that of IgM and IgA Levels of all three immunoglobulins in infants with birth weights less than 2 500 g as shown in Table 2 were similar to those in infants weighing more than 2 500 g

DISCUSSION

The results of the present study indicate that cell mediated immunity is significantly depressed in light for date infants—an observation similar to that reported by Chandra (3) The immunoglobulin levels on the other hand did not seem to be related to the birth weight of the infants This observation however is different from that of Chandra who found a significant decrease in IgG levels of infants with low birth weights Infants studied by Chandra however constitute a heterogeneous group and included premature babies It has been demonstrated by Berg (1) that IgG concentration is well correlated to gestational age but not to birth weight of infants The results presented here indicate that the immunoglobulin levels are not altered in full term light for date infants It must be pointed out however that these infants did not show severe intrauterine growth retardation There were only 3 infants weighing less than 2 000 g

These results suggest that all immunological functions are not equally sensitive to fetal malnutrition and parallel observations in older children with malnutrition as reported by Reddy et al (8) They do however show that infants with birth weights less than 2 500 g are likely to be at increased risk since they suffer from at least one immunological defect which may result in lowered resistance to infection

THE EFFECT OF CHOLESTYRAMINE ON SERUM LIPIDS AND PLATELET AGGREGATION OF HYPERCHOLESTEROLEMIC CHILDREN (TYPE II A) WHILE ON HIGH LINOLEIC ACID DIET

J FERNANDES R DIJKHUIS-STOFFELSMA and W F A GROSE

From the Department of Paediatrics Sophia Children s Hospital and Neonatal Unit Academic Hospital Erasmus University Rotterdam the Netherlands

ABSTRACT Fernandes J Dijkhuis-Stoffelsma R and Grose W F A (Department of Paediatrics Sophia Children s Hospital and Neonatal Unit Academic Hospital Erasmus University Rotterdam the Netherlands) The effect of cholestyramine on serum lipids and platelet aggregation of hypercholesterolemic children (type II A) while on high linoleic acid diet Acta Paediatr Scand 66 621 1977.—25 children with familial hypercholesterolemia (type II A) were treated with cholestyramine or placebo in a cross over study during 2 periods of each 10 weeks The medication was added to a high linoleic acid diet which had been started at least 1 year earlier Serum lipids and platelet aggregation were investigated at the end of the 2 periods On cholestyramine serum cholesterol levels decreased significantly whereas the linoleate and oleate content of cholesterylesters and serum triglycerides did not change systematically Platelet aggregation time measured with a filtragometer did not systematically change either

KEY WORDS Hypercholesterolemia cholestyramine high linoleic acid diet serum cholesterol serum triglycerides cholesterylesters platelet aggregation

Familial hypercholesterolemia Type II is associated with an increased risk of premature atherosclerosis (12 15) Reduction of the high serum cholesterol levels by a high linoleic acid diet (3) has successfully delayed death from occlusive vascular disease (13) and the results were more favourable the longer the dietary treatment had been applied (2) Early diagnosis and treatment in the pediatric age has therefore been recommended (5) Another issue has been the effect of a reduction of serum cholesterol by medication without diet (16) or by medication in addition to diet (5) on the life expectancy of children with familial hypercholesterolemia To approach this problem the mechanism of the atherosclerotic process has been more closely investigated Platelet adhesiveness might be an important factor in initiating atheromatous plaque formation and it has been demonstrated that linoleic acid enriched diets significantly reduce platelet aggregatability (4 7) Furthermore there is some evidence that a high linoleic acid concentration of serum cholesterylesters might decrease the tendency to human atherosclerosis (11) whereas a high oleic acid concentration could have the opposite effect (6) We focussed our attention on these aspects of the hypercholesterolemic state in those children in whom the dietary induced decrease of serum cholesterol was insufficient We administered cholestyramine or placebo in addition to the diet in order to know whether a further decrease of serum cholesterol by cholestyramine would be accompanied by changes in platelet aggregation and fatty acid composition of cholesterylesters

Table 1 *Serum cholesterol during high linoleic acid diet with cholestyramine or placebo added*

MATERIAL AND METHODS

The criteria for diagnosing hypercholesterolemia Type II were as follows all the children had serum cholesterol concentrations ranging from 7–11 mM Serum triglyceride concentrations were normal (<1 50 mM) Obesity and hypertension were not present Renal disease hypothyroidism diabetes mellitus and metabolic diseases were excluded

One parent of each of the children had hypercholesterolemia or had already died from cardiovascular disease We selected 25 children who had kept to a high linoleic acid diet during 1 to 3 years and whose serum cholesterol had decreased to a steady level The ages of the children were 4 to 14 years Two groups of 11 and 14 children were formed comparable as regards the patients age the severity of hypercholesterolemia and the linoleic acid content of the diet Siblings were present in both groups Cholestyramine was administered to one group placebo to the other After 10 weeks the medication of the 2 groups was reversed for another 10 weeks period The patients were not aware of the placebo prescription They consumed cholestyramine or placebo in a dose of 0 3 to 0 6 g per kg body weight per day This dose was divided in two parts for ingestion at breakfast and dinner Cholestyramine (Questran) and placebo were supplied on our request by Mead Johnson USA They contained 5 mg riboflavin per 4 g sachet This vitamin was added for its easy detection in the urine The qualitative assay of riboflavin in the urine (present or absent) thus facilitated the investigation of drug adherance of the patients in cases of doubt The patients diets during the 2 experimental periods remained the same as before The total fat content was approximately 30 cal% the linoleic acid content was 8 to 20 cal% the cholesterol intake was not more than 195 mg per day Medical examination of the patients with measurement of length and weight inquiry into adherance to the diet and the medication and laboratory investigations were carried out at the end of each 10 weeks period For each control visit the children were instructed to take a standard low fat breakfast in order to prevent prolonged fasting This low fat breakfast would presumably not influence the serum cholesterol level and platelet aggregation

METHODS

Serum cholesterol was determined according to Huang et al (9)

Serum triglycerides were determined according to Soloni (14)

For the fatty acid composition of cholesterylesters the procedure of Beukers et al (1) was followed using cholesteryl pentadecanoate as an internal standard in the organic solvent The cholesterylester band made visible with iodine vapor was scraped off and extracted with a chloroform methanol 1 1 mixture After evaporation of the solvents the esters were saponified with methanolic KOH at 65 C Cholesterol was removed by pentane extraction the water fraction was acidified and the free fatty acids were isolated by pentane extraction The solvent was evaporated and the acids were esterified with diazomethane in ether

The band on the thin layer plate containing the triglycerides was also isolated and extracted with a chloroform methanol 1 1 mixture containing pentadecanoic acid as a standard This extract was submitted to a similar procedure as described above

The gaschromatographic analyses were performed on a Hewlett Packard 402 gaschromatograph using dual 2 m 4 mm ID glass columns packed with 10% EGA on chromosorb W starting temperature 150°C final temperature 210°C program rate 2 C per min flash heater 170°C flame ionisation detector temperature 240°C Calculations were done with an on line Hewlett Packard 3352B computer

Platelet aggregation time was measured by the filtragometer procedure of Hornstra et al (7 8) With this method the aggregation of platelets in flowing blood is assessed by drawing blood via a polyethylene cannula from an anticubital vein through a microfilter into a motor driven syringe (diameter of the filter 2 3 mm pore size 20×70 µm flowrate of the blood 2 ml per min)

The filter s pores permit passage of red and white bloodcells and platelets but platelet aggregates occlude the pores Obstruction of the filter by platelet aggregates is reflected by an increasing difference between the blood pressures at both sides of the filter Aggregation time is the interval in seconds between venipuncture and obstruction of the filter (pressure difference at both sides of the filter ≥5 mmHg)

Riboflavin in the freshly voided morning urine was fluorometrically estimated at 524 nm in a Vitatron UFD 100 photometer with excitation at 443 nm A urine fluorescence of 30% or more in proportion to a standard solution of 10 mg/l riboflavin was considered to be positive

RESULTS

From interviews with the parents and from incidental testing of the patients urine for the presence of riboflavin it was deduced that the patients adherance to diet and medication was good Side effects of cholestyramine were similar to those reported by others Nausea or sensation of fullness could be mitigated by allowing 2 or 3 days for gradually increasing cholestyramine to the therapeutic dose of 0 3

to 0 6 g/kg/day Side effects such as steator rhea and low serum folate levels (16) were not investigated as the Questran doses were low and the medication lasted only 10 weeks

The serum cholesterol data are summarized in Table 1 The mean cholesterol concentra tion after 10 weeks of placebo added to the diet was 7 2 mmol/l after 10 weeks of Ques tran 6 0 mmol/l The difference between these data is highly significant $p<0\ 001$

The fatty acid composition of cholesteryles ters did not systematically change during the experiment for this reason only the means of the most important fatty acids i e linoleic acid and oleic acid and the oleic acid/linoleic acid ratio are summarized in Table 2

The serum triglyceride levels were normal in all children and did not systematically change during the experiment The linoleic acid and oleic acid percentages of serumtri glycerides and the oleic acid/linoleic acid ratio did not systematically change either (data not given) The data of platelet aggregation times are summarized in Table 3 The aggregation times were transformed to their logarithms for statistical treatment No systematic dif ferences were found between the two periods Other parameters for aggregation and disag gregation which can also be obtained from the filtragometry method of Hornstra (8) are not given as the number of patients in whom these data could be measured was too small

DISCUSSION

Addition of cholestyramine to a high linoleic acid diet successfully decreased the serum cholesterol concentrations of children with familial hypercholesterolemia (5) (Table 1) It is not known whether this has a favourable influence on the increased tendency to athero sclerotic disease of these patients We there fore investigated some factors which are in volved in atheromatous plaque formation One of these is platelet aggregatability which is known to be decreased by linoleic acid en riched diets (4 7) We did not find that the addition of cholestyramine to the diet had any effect on platelet aggregation time (Table 3)

It must be stressed however that our re sults were obtained with a filtragometer with a filter which has approximately the same pore size as the apparatus used in the original pub lications (7) and by others (4) but a smaller diameter Our experiments therefore need am plification using a larger group of patients and filtragometers with different filters Another important parameter for the atherosclerotic tendency seems to be the composition of cho lesterylesters Kingsbury et al (11) showed that patients with a reduced concentration of linoleic acid (<35%) subsequently had a higher incidence of myocardial infarction Gottenbos (6) suggested that not only the favourable effect of cholesterylester linoleate but also the unfavourable effect of cholesteryl ester oleate determine the tendency for athero sclerosis

In our study cholestyramine did not sys tematically influence cholesterylester linoleate

DISCUSSION

Addition of cholestyramine to a high linoleic acid diet successfully decreased the serum cholesterol concentrations of children with familial hypercholesterolemia (5) (Table 1) It is not known whether this has a favourable influence on the increased tendency to atherosclerotic disease of these patients We therefore investigated some factors which are involved in atheromatous plaque formation One of these is platelet aggregatability which is known to be decreased by linoleic acid enriched diets (4 7) We did not find that the addition of cholestyramine to the diet had any effect on platelet aggregation time (Table 3)

It must be stressed however that our results were obtained with a filtragometer with a filter which has approximately the same pore size as the apparatus used in the original publications (7) and by others (4) but a smaller diameter Our experiments therefore need amplification using a larger group of patients and filtragometers with different filters Another important parameter for the atherosclerotic tendency seems to be the composition of cholesterylesters Kingsbury et al (11) showed that patients with a reduced concentration of linoleic acid (<35%) subsequently had a higher incidence of myocardial infarction Gottenbos (6) suggested that not only the favourable effect of cholesterylester linoleate but also the unfavourable effect of cholesteryl ester oleate determine the tendency for atherosclerosis

In our study cholestyramine did not systematically influence cholesterylester linoleate

MATERIAL AND METHODS

The criteria for diagnosing hypercholesterolemia Type II were as follows all the children had serum cholesterol concentrations ranging from 7–11 mM Serum triglyceride concentrations were normal (<1 50 mM) Obesity and hypertension were not present Renal disease hypothyroidism diabetes mellitus and metabolic diseases were excluded

One parent of each of the children had hypercholesterolemia or had already died from cardiovascular disease We selected 25 children who had kept to a high linoleic acid diet during 1 to 3 years and whose serum cholesterol had decreased to a steady level The ages of the children were 4 to 14 years Two groups of 11 and 14 children were formed comparable as regards the patients age the severity of hypercholesterolemia and the linoleic acid content of the diet Siblings were present in both groups Cholestyramine was administered to one group placebo to the other After 10 weeks the medication of the 2 groups was reversed for another 10 weeks period The patients were not aware of the placebo prescription They consumed cholestyramine or placebo in a dose of 0 3 to 0 6 g per kg body weight per day This dose was divided in two parts for ingestion at breakfast and dinner Cholestyramine (Questran) and placebo were supplied on our request by Mead Johnson USA They contained 5 mg riboflavin per 4 g sachet This vitamin was added for its easy detection in the urine The qualitative assay of riboflavin in the urine (present or absent) thus facilitated the investigation of drug adherence of the patients in cases of doubt The patients diets during the 2 experimental periods remained the same as before The total fat content was approximately 30 cal% the linoleic acid content was 8 to 20 cal% the cholesterol intake was not more than 195 mg per day Medical examination of the patients with measurement of length and weight inquiry into adherance to the diet and the medication and laboratory investigations were carried out at the end of each 10 weeks period For each control visit the children were instructed to take a standard low fat breakfast in order to prevent prolonged fasting This low fat breakfast would presumably not influence the serum cholesterol level and platelet aggregation

METHODS

Serum cholesterol was determined according to Huang et al (9)

Serum triglycerides were determined according to Soloni (14)

For the fatty acid composition of cholesterylesters the procedure of Beukers et al (1) was followed using cholesteryl pentadecanoate as an internal standard in the organic solvent The cholesterylester band made visible with iodine vapor was scraped off and extracted with a chloroform methanol 1 1 mixture After evaporation of the solvents the esters were saponified with methanolic KOH at 65 C Cholesterol was removed by pentane extraction the water fraction was acidified and the free fatty acids were isolated by pentane extraction The solvent was evaporated and the acids were esterified with diazomethane in ether

The band on the thin layer plate containing the triglycerides was also isolated and extracted with a chloroform methanol 1 1 mixture containing pentadecanoic acid as a standard This extract was submitted to a similar procedure as described above

The gaschromatographic analyses were performed on a Hewlett Packard 402 gaschromatograph using dual ? m 4 mm ID glass columns packed with 10% EGA on chromosorb W starting temperature 150°C final temperature 210°C program rate 2 C per min flash heater 170°C flame ionisation detector temperature 240°C Calculations were done with an on line Hewlett Packard 3352B computer

Platelet aggregation time was measured by the filtragometer procedure of Hornstra et al (7 8) With this method the aggregation of platelets in flowing blood is assessed by drawing blood via a polyethylene cannula from an anticubital vein through a microfilter into a motor driven syringe (diameter of the filter 2 3 mm pore size 20×20 μm flowrate of the blood 2 ml per min)

The filter s pores permit passage of red and white bloodcells and platelets but platelet aggregates occlude the pores Obstruction of the filter by platelet aggregates is reflected by an increasing difference between the blood pressures at both sides of the filter Aggregation time is the interval in seconds between venipuncture and obstruction of the filter (pressure difference at both sides of the filter ≥5 mmHg)

Riboflavin in the freshly voided morning urine was fluorometrically estimated at 524 nm in a Vitatron UFD 100 photometer with excitation at 443 nm A urine fluorescence of 30% or more in proportion to a standard solution of 10 mg/l riboflavin was considered to be positive

RESULTS

From interviews with the parents and from incidental testing of the patients urine for the presence of riboflavin it was deduced that the patients adherance to diet and medication was good Side effects of cholestyramine were similar to those reported by others Nausea or sensation of fullness could be mitigated by allowing 2 or 3 days for gradually increasing cholestyramine to the therapeutic dose of 0 3

to 0 6 g/kg/day Side effects such as steator rhea and low serum folate levels (16) were not investigated as the Questran doses were low and the medication lasted only 10 weeks

The serum cholesterol data are summarized in Table 1 The mean cholesterol concentra tion after 10 weeks of placebo added to the diet was 7 2 mmol/l after 10 weeks of Ques tran 6 0 mmol/l The difference between these data is highly significant $p<0\ 001$

The fatty acid composition of cholesteryles ters did not systematically change during the experiment for this reason only the means of the most important fatty acids i e linoleic acid and oleic acid and the oleic acid/linoleic acid ratio are summarized in Table 2

The serum triglyceride levels were normal in all children and did not systematically change during the experiment The linoleic acid and oleic acid percentages of serumtri glycerides and the oleic acid/linoleic acid ratio did not systematically change either (data not given) The data of platelet aggregation times are summarized in Table 3 The aggregation times were transformed to their logarithms for statistical treatment No systematic dif ferences were found between the two periods Other parameters for aggregation and disag gregation which can also be obtained from the filtragometry method of Hornstra (8) are not given as the number of patients in whom these data could be measured was too small

RESULTS

From interviews with the parents and from incidental testing of the patients urine for the presence of riboflavin it was deduced that the patients adherance to diet and medication was good Side effects of cholestyramine were similar to those reported by others Nausea or sensation of fullness could be mitigated by allowing 2 or 3 days for gradually increasing cholestyramine to the therapeutic dose of 0

to 0 6 g/kg/day Side effects such as steatorrhea and low serum folate levels (16) were not investigated as the Questran doses were low and the medication lasted only 10 weeks

The serum cholesterol data are summarized in Table 1 The mean cholesterol concentration after 10 weeks of placebo added to the diet was 7 2 mmol/l after 10 weeks of Questran 6 0 mmol/l The difference between these data is highly significant $p<0\ 001$

The fatty acid composition of cholesterylesters did not systematically change during the experiment for this reason only the means of the most important fatty acids i e linoleic acid and oleic acid and the oleic acid/linoleic acid ratio are summarized in Table 2

The serum triglyceride levels were normal in all children and did not systematically change during the experiment The linoleic acid and oleic acid percentages of serumtriglycerides and the oleic acid/linoleic acid ratio did not systematically change either (data not given) The data of platelet aggregation times are summarized in Table 3 The aggregation times were transformed to their logarithms for statistical treatment No systematic differences were found between the two periods Other parameters for aggregation and disaggregation which can also be obtained from the filtragometry method of Hornstra (8) are not given as the number of patients in whom these data could be measured was too small

DISCUSSION

Addition of cholestyramine to a high linoleic acid diet successfully decreased the serum cholesterol concentrations of children with familial hypercholesterolemia (5) (Table 1) It is not known whether this has a favourable influence on the increased tendency to atherosclerotic disease of these patients We therefore investigated some factors which are involved in atheromatous plaque formation One of these is platelet aggregatability which is known to be decreased by linoleic acid enriched diets (4 7) *We did not find that the* addition of cholestyramine to the diet had any effect on platelet aggregation time (Table 3)

It must be stressed however that our results were obtained with a filtragometer with a filter which has approximately the same pore size as the apparatus used in the original publications (7) and by others (4) but a smaller diameter Our experiments therefore need amplification using a larger group of patients and filtragometers with different filters Another important parameter for the atherosclerotic tendency seems to be the composition of cholesterylesters Kingsbury et al (11) showed that patients with a reduced *concentration* of linoleic acid (<35%) subsequently had a higher incidence of myocardial infarction Gottenbos (6) *suggested* that not only the favourable effect of cholesterylester linoleate but also the unfavourable effect of cholesteryl ester oleate determine the tendency for atherosclerosis

In our study cholestyramine did not systematically influence cholesterylester linoleate

and oleate concentrations during a high linoleic acid diet (Table 2) We have no explanation for the fact that the 2 groups matched for age and serum cholesterol levels of the patients and the linoleic acid content of the diets had different mean percentages of linoleic acid of cholesterylesters (48 and 54% respectively) These percentages increased in both groups (to 50 and 58% respectively) despite the cross over design of the study This increase of the linoleic acid percentages in both groups is most likely due to a time effect

It has previously been found that another cholesterol lowering agent (Clofibrate) reduced linoleate and increased oleate concentrations of cholesterylesters (10) It might be argued that cholestyramine though not influencing the oleate/linoleate proportion of cholesterylesters could augment the effect of a high linoleic acid diet by decreasing the total amount of cholesterol and thus the amount of cholesterylester oleate

From our data and those of others we may conclude the following cholestyramine, added to a high linoleic acid diet augments the cholesterol lowering effect of the diet but has no effect on platelet aggregation nor on the relative linoleate and oleate content of cholesterylesters and triglycerides It use could be considered in those children who remain severely hypercholesterolemic despite the ingestion of a high linoleic acid diet

PREVENTION OF KERNICTERUS BASED ON RECENT PROGRESS IN BILIRUBIN CHEMISTRY

R BRODERSEN

From the Institute of Medical Biochemistry University of Aarhus Aarhus Denmark

ABSTRACT Brodersen R (Institute of Medical Biochemistry University of Aarhus, Aarhus Denmark) Prevention of kernicterus based on recent progress in bilirubin chemistry Acta Paediatr Scand 66 625 1977 —A review is presented of recent progress in bilirubin chemistry its binding to albumin displacement by drugs and the mechanism of phototherapy Quantitative formulations of the effect of albumin dosage of varying pH and of fatty acids result in a diagram which may be tried as an aid to indications for therapy

KEY WORDS Albumin alkali therapy bilirubin displacement bilirubin isomers exchange transfusion fatty acids kernicterus phototherapy

Free bilirubin from plasma may penetrate the basal ganglia and cause yellow staining kernicterus or may in non fatal cases give lasting brain damage of varying severity Avoidance of neurotoxic levels of free bilirubin is accordingly an important pediatric concern and may be aided by recently acquired knowledge of the chemistry of bilirubin and its binding to albumin as outlined in the present review

Chemical structure of bilirubin Solubility and neurotoxicity

X ray crystallographic studies by Bonnett et al (6) have shown that crystalline bilirubin the acid form has the structure shown in Fig 1 The side chains are in the IX-α position and the double bonds adjacent to the outer rings are in the Z-configuration (compare Fig 4 which shows the E configuration) Intramolecular hydrogen bonds (stippled lines in Fig 1) saturate the hydrophilic groups of the molecule leaving no affinities for attachment of water This substance the acid form of bilirubin IX-α(Z) is therefore nearly insoluble in water

In an alkaline medium the hydrogen bonds are opened forming the divalent anion (Fig 2) which has several hydrophilic groups i e two carboxylate four pyrrol N and two C=O and forms soluble salts At pH 7 4 the solubility of bilirubin IX α(Z) is low of the order of 0 1 μmol/l (18) increasing steeply in more alkaline media

According to McDonagh & Assisi (32) the bilirubin anion in aqueous solution is cleaved slowly at the central methylene bridge and is reunited at random forming a mixture containing two additional isomers III α and XIII α (abbreviated formulae shown in Fig 3*b* c) These are found together with bilirubin IX α(Z) in some commercial bilirubin preparations (31) while only one of these the IX α(Z) isomer has been found *in vivo*

Recent work in Heirwegh s laboratory (3 4 5 24) has shown that small amounts of three

and oleate concentrations during a high linoleic acid diet (Table 2) We have no explanation for the fact that the 2 groups, matched for age and serum cholesterol levels of the patients and the linoleic acid content of the diets had different mean percentages of linoleic acid of cholesterylesters (48 and 54% respectively) These percentages increased in both groups (to 50 and 58% respectively) despite the cross over design of the study This increase of the linoleic acid percentages in both groups is most likely due to a time effect

It has previously been found that another cholesterol lowering agent (Clofibrate) reduced linoleate and increased oleate concentrations of cholesterylesters (10) It might be argued that cholestyramine though not influencing the oleate/linoleate proportion of cholesterylesters could augment the effect of a high linoleic acid diet by decreasing the total amount of cholesterol and thus the amount of cholesterylester oleate

From our data and those of others we may conclude the following cholestyramine added to a high linoleic acid diet augments the cholesterol lowering effect of the diet but has no effect on platelet aggregation nor on the relative linoleate and oleate content of cholesterylesters and triglycerides It use could be considered in those children who remain severely hypercholesterolemic despite the ingestion of a high linoleic acid diet

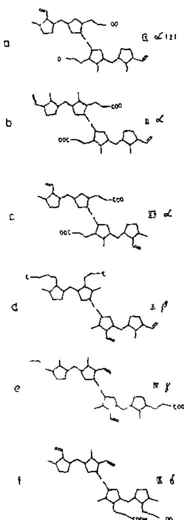

Fig 3 Abbreviated formulae omitting hydrogen bonds of bilirubin isomers Bilirubins III-α and XIII-α are found in some commercial preparations but not in vivo The IX β IX γ and IX-δ isomers are present in small amounts in the human body are soluble excreted without conjugation and are presumably non toxic

around 400 μmol/l b_0 is of the order of 50 nmol/l Concentrations of free bilirubin IX α(Z) higher than this figure could cause kernicterus

A somewhat better definition of the safe upper limit of free bilirubin concentration may be obtained from the work of Wennberg et al (45) These investigators used the peroxidase technique described by Jacobsen & Wennberg (30) on a large number of serum samples at 27° and found that kernicterus did not occur at a free bilirubin concentration less than 20 nmol/l Correction to 37 utilizing the temperature dependence of the binding constant as determined by Jacobsen (28) results in multiplication of this figure by 2 5 giving 50 nmol/l as above These findings suggest that the safe upper limit of free bilirubin IX α(Z) concentration is indeed about 50 nmol/l

It is interesting to note that this level of free bilirubin is reached when 78% of the albumin high affinity site is saturated with bilirubin Full saturation of the high affinity site would give a very high value of free bilirubin and is not thermodynamically possible When binding to secondary sites is taken into account it is found (14 15) that one mole of albumin is capable of carrying a maximum of 1 0 mole of bilirubin IX α(Z) If an occasional bilirubin concentration higher than the molar concentration of albumin is encountered in the clinic the presence of soluble bilirubin isomers or conjugates should be considered

Analytical methods for determination of the concentration of free bilirubin IX α(Z) in undiluted blood plasma or serum are not available at present (10) The Sephadex technique is not specific since bilirubin conjugates are adsorbed the soluble bilirubin isomers are probably also adsorbed The peroxidase method (30) is less sensitive to errors caused by the presence of other bilirubins A small

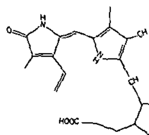

Fig 4 Bilirubin IX-α(E) (one half of the molecule shown) formed by irradiation with blue light of bilirubin IX α(Z) bound to serum albumin through rotation of the outer ring at the double bond This isomer is also soluble and presumably non toxic

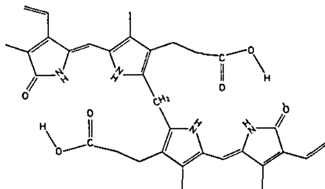

Fig 1 The main bile pigment in the human body bilirubin IX α(Z) in its acid form An array of intramolecular hydrogen bonds (stippled lines) is characteristic for this substance and is essential for its insolubility and its neurotoxicity

other bilirubins IX β IX γ and IX δ, are formed in the body besides the main pigment IX α(Z) by breaking the porphyrin rings in different positions (Fig 3*d* *e* and *f*) Still another isomer bilirubin IX α(E) (Fig 4) (Pedersen et al (37)) is probably a product of bilirubin transformation by phototherapy In all four of these isomers the carboxyl groups are shifted in relation to the other polar groups These substances therefore do not form the intramolecular hydrogen bonds which are present in bilirubin IX-α(Z) and are consequently soluble in water even in neutral or acid media

Soluble bilirubin isomers are excreted as such in bile or urine (25) whilst the slightly soluble bilirubin IX-α(Z) which accounts for the major part of excreted bile pigment is conjugated with glucuronic acid glucose or xylose forming soluble derivatives (24) The conjugation–excretion function of the liver is incompletely developed in the neonate so that bilirubin IX α(Z) accumulates during the first few days of life resulting in physiological neonatal jaundice

In summary the following bilirubins may be found in the human body IX α(Z) IX β IX γ IX δ, IX α(E), and conjugates of bilirubin IX α(Z) with glucuronic acid glucose and xylose Only one of these bilirubin IX α(Z) has a low solubility in water, due to the intra molecular hydrogen bonds, and only this compound is known to be neurotoxic The toxicity as outlined below probably depends upon precipitation of the insoluble acid form of this pigment in subcellular structures All the other substances are soluble and may presumably be regarded as non toxic (although experimental data on the toxicity of the newly discovered isomers are lacking)

Binding to albumin

Free bilirubin concentration

Bilirubin IX α(Z) is bound reversibly to one high affinity site on human serum albumin The binding constant at 37° is 7×10 mol/l (27 14) *Binding to two secondary sites seems* to play a minor role (14) If no other substances are bound to the same site it is possible to calculate the equilibrium concentration of free bilirubin IX α(Z) as

$$b_0=\frac{1}{7\times10^7}\times\frac{B}{A-B} \qquad (1)$$

where b_0 is the concentration of free bilirubin IX α(Z) in the absence of a competitor and A and B are the concentrations of albumin and bilirubin respectively In the average adult when $A=700$ μmol/l and $B=6$ μmol/l b_0 is $1\ 2\times10^{-10}$ mol/l or 0 12 nmol/l Considerably higher concentrations *of free bilirubin IX α(Z)* are found in icteric infants At a serum bilirubin concentration approaching the limit where exchange transfusion is considered when B is 310 μmol/l (18 mg/100 ml) and A

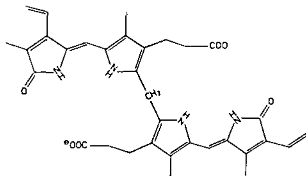

Fig 2 The anion of bilirubin IX-α(Z) which forms soluble salts in alkaline media

dose of 1 g/kg (400 μmol/l when distributed in the plasma volume) given to an infant with a critical level of free bilirubin immediately causes a reduction of the free bilirubin concentration from 50 to 10 nmol/l Bilirubin is then retracted from the brain and other tissues into the blood plasma resulting in an increase of plasma bilirubin concentration the so-called *rebound* phenomenon The degree of rebound gives a measure of the benefit obtained from treatment If an infant before administration of albumin was heavily loaded with bilirubin the final result after about one hour is likely to be a considerable increase in plasma bilirubin concentration with a decrease of free bilirubin and a consequent reduction of neurotoxicity

Albumin may be given as whole blood with exchange transfusion A major part of the effect obtained by this measure must be ascribed to the albumin Commercial albumin preparations have been used by several investigators (36 46 19) as an isolated treatment or more often before exchange transfusion with the aim of increasing the amount of bilirubin removed when blood is subsequently drawn from the infant The results have generally been less favourable than expected from the above theoretical considerations and it is possible that the failures may be explained by the presence of stabilizers in commercial albumin preparations (16) Caprylate *N* acetyl tryptophan or both are added to stabilize the protein during heating for inactivation of hepatitis virus and are left in the final product These substances occupy the bilirubin binding site on the albumin and cause a decrease of the immediate bilirubin binding effect or even a temporary reversal with a transient increase of free bilirubin in the blood stream It is technically possible to prepare albumin without a large content of stabilizers and such preparations should be tried in impending kernicterus

The importance of pH

The risk of brain damage is increased in acidosis ((43) and references therein) Silberberg et al (39) in 1970 pointed out that this may be explained either by increased binding of bilirubin to the target or by decreased affinity of the binding to albumin Bilirubin binding to mitochondria to red blood cells and to fibroblasts in tissue culture is increased by lowering pH (7 34 35) while the bilirubin binding affinity to its first site on albumin is unchanged (29) Recalculation of the results of Brathd (7) for binding to erythrocytes shows that the binding constant is approximately proportional to the square of the hydrogen ion concentration Since bilirubin has two acid carboxyl groups with pK around 4 and shows no further acid dissociation even at a high pH (23) the binding of bilirubin to erythrocytes may be described as binding of the undissociated bilirubin acid with high affinity It seems likely that this mechanism is operative also at structures where the toxic effect is manifested

Binding to albumin occurs by an entirely different mechanism the divalent bilirubin anion is bound without participation of hydrogen ions and the affinity is therefore constant with varying pH This means that the safe limit of free bilirubin concentration varies with pH as described by the equation

$$\log \frac{\text{lim}\, b(\text{pH})}{50\ \text{nmol/l}} = 2(\text{pH} - 7\ 40) \qquad (2)$$

where lim b(pH) is the safe upper limit of the free concentration of bilirubin IX α(Z) at the actual pH when 50 nmol/l is provisionally taken as the safe limit at pH 7 40

This concept could alternatively be stated by saying that what is toxic is not the free bilirubin anion but free bilirubin acid The acid is present in plasma in equilibrium with the divalent anion The ratio of acid to anion at normal pH is of the order of 10^{-6} and is inversely proportional to the square of the hydrogen ion concentration At a constant level of neurotoxicity i e at a constant concentration of the free bilirubin acid the concentration of the free anion varies considerably with pH and the albumin is accordingly capable of

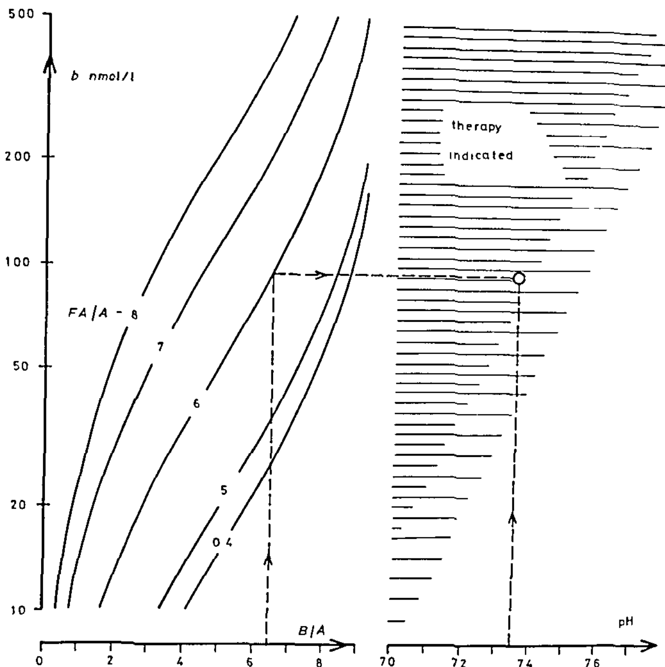

Fig 5 A diagram showing theoretically calculated indications for exchange transfusion in neonatal icterus based on measurements of bilirubin (*B*) albumin (*A*) and fatty acid (FA) concentrations (all in molarities) and pH in the blood plasma The calculated concentration of free bilirubin IX α(Z) is indicated in the ordinate The use of the diagram is exemplified by the stippled lines If other displacers than fatty acids are present exchange transfusion may be necessary even when not indicated by the diagram

amount (about 1%) of a conjugated or soluble bilirubin isomer may be oxidized ahead of bilirubin IX α(Z) without causing serious error This technique is probably the best approach to determination of free bilirubin IX α(Z) in diluted serum samples The dilution which is necessary for technical reasons does not change the equilibrium concentration of free bilirubin in a system of the pure components but abolishes the effect of weakly bound competitors such as displacing drugs resulting in misleadingly low figures if competing drugs are present in the blood sample

The use of albumin in therapy and prevention

As seen from eq (1) the free bilirubin concentration may be reduced by giving albumin A

dose of 1 g/kg (400 μmol/l when distributed in the plasma volume) given to an infant with a critical level of free bilirubin immediately causes a reduction of the free bilirubin concentration from 50 to 10 nmol/l Bilirubin is then retracted from the brain and other tissues into the blood plasma resulting in an increase of plasma bilirubin concentration the so-called *rebound* phenomenon The degree of rebound gives a measure of the benefit obtained from treatment If an infant before administration of albumin was heavily loaded with bilirubin the final result after about one hour is likely to be a considerable increase in plasma bilirubin concentration with a decrease of free bilirubin and a consequent reduction of neurotoxicity

Albumin may be given as whole blood with *exchange transfusion* A major part of the effect obtained by this measure must be ascribed to the albumin Commercial albumin preparations have been used by several investigators (36 46 19) as an isolated treatment or more often before exchange transfusion with the aim of increasing the amount of bilirubin removed when blood is subsequently drawn from the infant The results have generally been less favourable than expected from the above theoretical considerations and it is possible that the failures may be explained by the presence of stabilizers in commercial albumin preparations (16) Caprylate N acetyl tryptophan or both are added to stabilize the protein during heating for inactivation of hepatitis virus and are left in the final product These substances occupy the bilirubin binding site on the albumin and cause a decrease of the immediate bilirubin binding effect or even a temporary reversal with a transient *increase of* free bilirubin in the blood stream It is technically possible to prepare albumin without a large content of stabilizers and such preparations should be tried in impending kernicterus

The importance of pH

The risk of brain damage is increased in acidosis ((43) and references therein) Silberberg et al (39) in 1970 pointed out that this may be explained either by increased binding of bilirubin to the target or by decreased affinity of the binding to albumin Bilirubin binding to mitochondria to red blood cells and to fibroblasts in tissue culture is increased by lowering pH (7 34 35) while the bilirubin binding affinity to its first site on albumin is unchanged (29) Recalculation of the results of Bratlid (7) for binding to erythrocytes shows that the binding constant is approximately proportional to the square of the hydrogen ion concentration Since bilirubin has two acid carboxyl groups with pK around 4 and shows no further acid dissociation even at a high pH (23) the binding of bilirubin to erythrocytes may be described as binding of the undissociated bilirubin acid with high affinity It seems likely that this mechanism is operative also at structures where the toxic effect is manifested

Binding to albumin occurs by an entirely different mechanism the divalent bilirubin anion is bound without participation of hydrogen ions and the affinity is therefore constant with varying pH This means that the safe limit of free bilirubin concentration varies with pH as described by the equation

$$\log \frac{\lim b(\mathrm{pH})}{50\ \mathrm{nmol/l}} = 2(\mathrm{pH} - 7\ 40) \quad (2)$$

where $\lim b(\mathrm{pH})$ is the safe upper limit of the free concentration of bilirubin IX α(Z) at the actual pH when 50 nmol/l is provisionally taken as the safe limit at pH 7 40

The importance of pH

The risk of brain damage is increased in acidosis ((43) and references therein) Silberberg et al (39) in 1970 pointed out that this may be explained either by increased binding of bilirubin to the target or by decreased affinity of the binding to albumin Bilirubin binding to mitochondria to red blood cells and to fibroblasts in tissue culture is increased by lowering pH (7 34 35) while the bilirubin binding affinity to its first site on albumin is unchanged (29) Recalculation of the results of Brathd (7) for binding to erythrocytes shows that the binding constant is approximately proportional to the square of the hydrogen ion concentration Since bilirubin has two acid carboxyl groups with pK around 4 and shows no further acid dissociation even at a high pH (23) the binding of bilirubin to erythrocytes may be described as binding of the undissociated bilirubin acid with high affinity It seems likely that this mechanism is operative also at structures where the toxic effect is manifested

Binding to albumin occurs by an entirely different mechanism the divalent bilirubin anion is bound without participation of hydrogen ions and the affinity is therefore constant with varying pH This means that the safe limit of free bilirubin concentration varies with pH as described by the equation

$$\log \frac{\text{lim}\,b(\text{pH})}{50\ \text{nmol/l}} = 2(\text{pH} - 7\ 40) \qquad (2)$$

where lim$b$(pH) is the safe upper limit of the free concentration of bilirubin IX-α(Z) at the actual pH when 50 nmol/l is provisionally taken as the safe limit at pH 7 40

This concept could alternatively be stated by saying that what is toxic is not the free bilirubin anion but free bilirubin acid The acid is present in plasma in equilibrium with the divalent anion The ratio of acid to anion at normal pH is of the order of 10^{-6} and is inversely proportional to the square of the hydrogen ion concentration At a constant level of neurotoxicity i e at a constant concentration of the free bilirubin acid the concentration of the free anion varies considerably with pH and the albumin is accordingly capable of

carrying more bilirubin at a higher pH without risk of toxicity

In severe acidosis (plasma pH 7 05) the safe limit is thus 10 nmol/l whilst it is 100 nmol/l at pH 7 55 This is in good agreement with clinical experience and suggests that correc tion of plasma pH even to slightly above the normal level might be considered a fast and safe measure in the prevention of kernicterus The effect can again be measured by the bili rubin rebound An infant with a plasma pH 7 05 and a safe upper level of 10 nmol/l free bilirubin has plasma albumin less than half saturated with bilirubin (equation (1)) and has a bilirubin concentration about 150 to 200 μmol/l (9–12 mg/100 ml) After correction of pH the equilibrium is shifted in favour of the plasma albumin which can now carry a bili rubin concentration in the neighborhood of 300 to 400 μmol/l (18–24 mg/100 ml) and yet still have a tolerable level of the free pigment If an extracellular excess of bilirubin was pres ent before therapy success of the treatment should be signalled by an increase of plasma bilirubin concentration

Displacement of bilirubin by fatty acids

The amounts of long chain fatty acids nor mally present in plasma can be transported bound to albumin without interfering with bili rubin transport whilst fatty acid levels higher than four times the molar concentration of al bumin displace bilirubin from its primary bind ing site (41 47 20 44) Such fatty acid con centrations may be seen in certain disease states (21) and notably after parenteral nour ishment with fat emulsion (48) Andrew et al (1) using the Sephadex method for demon strating increased levels of free bilirubin have recommended that the molar ratio of fatty acid to albumin in the blood plasma be kept below 6 An empirical equation (14) derived from *in vitro* studies using the peroxidase technique can be used for estimation of the free bilirubin level during fatty acid loads i e when the fatty acid/albumin ratio is above 4 6

$$\frac{b}{b_0}=1\ 16(\mathrm{FA}/A-4\ 6)^{*}+1 \qquad (3)$$

where b is the free bilirubin concentration in the presence of fatty acid b_0 is calculated from equation (1), and FA is the molar con centration of long-chain fatty acids in the plasma It is seen that 6 mol fatty acid per mol albumin already appears to increase the free bilirubin concentration by a factor 2 6 while 5 mol seems to be permissible Final assessment of safe limits of fatty acid con centration must await an accepted method for determination of free bilirubin IX-α(Z) in un diluted plasma

A diagrammatic aid to indications for therapy

The above considerations are summarized in Fig 5 which comprises equations (1) (2) and (3) The diagram is used as follows Uncon jugated bilirubin albumin non esterified fatty acid and pH are measured in the infant s plasma (A small amount c 5% of bilirubin isomers and conjugates included in the bili rubin determination causes no serious error) The molar ratio of bilirubin to albumin B/A is calculated and entered on the abscissa in the left half of the diagram The fatty acid to al bumin molar ratio FA/A is used for selection of one of the curves The ordinate now indi cates the calculated concentration of free bili rubin IX α(Z) Keeping the same ordinate and entering the value of pH in the right half of the diagram leads to a point which may fall in the white the lightly shaded or the heavily shaded area A point in the white area shows that the plasma bilirubin concentration at the actual values of albumin fatty acid and pH does not indicate treatment A suggestive in dication exists in the intermediate area and a definite indication for therapy exchange transfusion albumin or alkali is present if the point falls in the dark upper left triangle An example (stippled lines) illustrates the pro- cedure

The borders between the three areas repre

sent free bilirubin IX α(Z) concentrations of 50 and 100 nmol/l respectively at pH 7 40 These limits are provisional and must be fixed by clinical experience and comparison with other systems of criteria for exchange trans fusion

The proposed method has limitations in be ing unable to take into account the effects of displacing drugs or of endogenous displac ing substances as well as other factors such as prematurity a history of previous anoxia etc

Displacing drugs

Certain sulfonamides and a number of other drugs can competitively displace bilirubin from its binding site on albumin thus increas ing the risk of kernicterus Clinical experience has shown that sulfisoxazole is capable of precipitating kernicterus in icteric infants (40) As pointed out by Stern (42) all drugs used in newborns or in pregnant or lactating women should be examined for bilirubin displacing effect This effect should be expressed in quantitative terms since many drugs are weak displacers (12 9) and some exert considerable displacement when given in large doses while being harmless in smaller amounts

The bilirubin displacement can be calcu lated from the equation

$$\frac{b}{b_0} = K_D d + 1 \quad (4)$$

where b is the free bilirubin IX-α(Z) concen tration in the presence of a displacing drug b_0 is calculated from equation (1) K_D is the binding constant of the drug to the bilirubin site on the albumin molecule and d is the free drug concentration in the plasma K_D is a con stant characteristic for each competitive drug which can be determined experimentally by the peroxidase technique (8) or by a double equilibrium dialysis against albumin and against albumin with one mol of bound bili rubin (13) Twenty sulfonamides have been examined by both methods Good agreement was obtained confirming the validity of either technique The peroxidase method is by far the easier and about two hundred substances mostly drugs have been tested In summary the results are as follows

The *sulfonamides* (13) show widely differing displacing effects ranging from strong dis placement with sulfaphenazole and sulfisoxa zole to a slight competition seen with sulfadia zine The latter compound appears safe at usual plasma levels and would be the drug of choice if a sulfonamide is given to an icteric newborn

Several *analgesic and antiinflammatory substances* are bilirubin displacers Some of these including salicylate (8 11 26) na proxen and phenylbutazone (12) have little effect at usual plasma levels but displace sig nificantly at higher concentrations Further studies with this group of substances are in dicated

Dicoumarol showed strong displacement in preliminary experiments Detailed work is needed with this and other anticoagulants

The strongest displacement was encoun tered with *X ray contrast media for cholangio graphy* These are used at very high plasma concentrations and are tailored to bind to al bumin in order to avoid excretion in the urine Binding includes the bilirubin site

Other compounds including the *benzodia zepines* are bound strongly to albumin but at a different site so they do not displace bili rubin (17)

The displacing effect of *stabilizers* in inject able albumin solutions (16) has been men tioned above Also the *parabenes* often used as antibacterial preservatives show significant displacement (8 38) These substances are used in large amounts as *food additives* so also is saccharin another bilirubin displacer Special attention is indicated if food additives are present in milk preparations used during the first few days of life and additives in the food of pregnant and lactating women should also be considered Although kernicterus has not been ascribed to these substances the possibility of minor brain damage should be

carrying more bilirubin at a higher pH without risk of toxicity

In severe acidosis (plasma pH 7 05) the safe limit is thus 10 nmol/l whilst it is 100 nmol/l at pH 7 55 This is in good agreement with clinical experience and suggests that correction of plasma pH even to slightly above the normal level might be considered a fast and safe measure in the prevention of kernicterus The effect can again be measured by the bilirubin rebound An infant with a plasma pH 7 05 and a safe upper level of 10 nmol/l free bilirubin has plasma albumin less than half saturated with bilirubin (equation (1)) and has a bilirubin concentration about 150 to 200 μmol/l (9–12 mg/100 ml) After correction of pH the equilibrium is shifted in favour of the plasma albumin which can now carry a bilirubin concentration in the neighborhood of 300 to 400 μmol/l (18–24 mg/100 ml) and yet still have a tolerable level of the free pigment If an extracellular excess of bilirubin was present before therapy success of the treatment should be signalled by an increase of plasma bilirubin concentration

Displacement of bilirubin by fatty acids

The amounts of long chain fatty acids normally present in plasma can be transported bound to albumin without interfering with bilirubin transport whilst fatty acid levels higher than four times the molar concentration of albumin displace bilirubin from its primary binding site (41 47 20 44) Such fatty acid concentrations may be seen in certain disease states (21) and notably after parenteral nourishment with fat emulsion (48) Andrew et al (1) using the Sephadex method for demonstrating increased levels of free bilirubin have recommended that the molar ratio of fatty acid to albumin in the blood plasma be kept below 6 An empirical equation (14) derived from *in vitro* studies using the peroxidase technique can be used for estimation of the free bilirubin level during fatty acid loads i e when the fatty acid/albumin ratio is above 4 6

$$\frac{b}{b_0}=1\ 16(FA/A-4\ 6)+1 \qquad (3)$$

where b is the free bilirubin concentration in the presence of fatty acid, b_0 is calculated from equation (1) and FA is the molar concentration of long chain fatty acids in the plasma It is seen that 6 mol fatty acid per mol albumin already appears to increase the free bilirubin concentration by a factor 2 6 while 5 mol seems to be permissible Final assessment of safe limits of fatty acid concentration must await an accepted method for determination of free bilirubin IX α(Z) in undiluted plasma

A diagrammatic aid to indications for therapy

The above considerations are summarized in Fig 5, which comprises equations (1) (2) and (3) The diagram is used as follows Unconjugated bilirubin albumin non esterified fatty acid and pH are measured in the infant s plasma (A small amount c 5% of bilirubin isomers and conjugates included in the bilirubin determination causes no serious error) The molar ratio of bilirubin to albumin B/A is calculated and entered on the abscissa in the left half of the diagram The fatty acid to albumin molar ratio FA/A is used for selection of one of the curves The ordinate now indicates the calculated concentration of free bilirubin IX α(Z) Keeping the same ordinate and entering the value of pH in the right half of the diagram leads to a point which may fall in the white the lightly shaded or the heavily shaded area A point in the white area shows that the plasma bilirubin concentration at the actual values of albumin fatty acid and pH does not indicate treatment A suggestive indication exists in the intermediate area and a definite indication for therapy exchange transfusion albumin or alkali is present if the point falls in the dark upper left triangle An example (stippled lines) illustrates the procedure

kept in mind, since food additives are given to large populations, sometimes in considerable amounts and usually without declaration.

The majority of drugs tested showed little or no displacing effect. Most *antibiotics* (with the possible exception of some penicillin derivatives), *antihistamines*, *diuretics* and *general anaesthetics* so far investigated proved harmless. All *drugs carrying a positive net charge* were found not to be displacing.

Many drugs are given in small amounts, such as *hormones*, some of the *synthetic diuretics*, *digitoxin*, etc., and these will not displace bilirubin significantly, even if they are bound strongly to the bilirubin site, because the molar concentration available in the blood plasma is very small compared to that of albumin. It is unnecessary to examine the displacing effect of such compounds.

A certain reservation is necessary when applying these *in vitro* results to clinical practice. Metabolites of drugs may displace more strongly than the compounds administered. This has been found with sulfonamides (13) which are metabolized predominantly by *N*(4) acetylation in the newborn infant. Seven *N*(4) acetylated sulfonamides have been tested and all these showed displacing effects equal to or stronger than those of the mother compounds. A hydroxylated metabolite of phenylbutazone appears to be a very strong displacer (12). It would therefore be very useful if a test could be designed to assess the displacing effect of drugs in the human body. Studies in Gunn rats (2, 22, 33) may also give suggestive results, although it must be remembered that the pattern of drug metabolism and binding to albumin often shows species differences.

Albumin therapy against bilirubin displacement

In the case of suspected bilirubin displacement, whether caused by fatty acids, by endogenous displacers, or by competitive drugs, a rational therapy is intravenous administration of albumin. More binding sites are then provided for bilirubin as well as for the competitor and, in case of exchange transfusion, certain amounts of both substances are removed from the body.

It should be noted that the plasma bilirubin concentration before treatment is likely to be low in these cases. If 6 mol fatty acid is present per mol albumin, a free bilirubin concentration of 50 nmol/l is reached when half of the albumin is occupied by bilirubin, as seen from the diagram (Fig. 5). Similar figures are obtained after sulfisoxazole in usual dosage (8). At usual levels of albumin, this occurs at a bilirubin concentration about 200 to 250 μmol/l (12–15 mg/100 ml) and therapy is needed if the plasma bilirubin is above this. The indication for treatment, therefore, cannot be obtained by determination of plasma bilirubin alone and, when displacers other than fatty acids are present, also not by use of the diagram. A method for quantitative determination of free bilirubin IX α(Z) in undiluted blood plasma would be helpful. The result of this determination could be entered as the ordinate in the diagram (Fig. 5) and would, together with the plasma pH in the abscissa, contribute rationally to the clinician's decision.

kept in mind, since food additives are given to large populations sometimes in considerable amounts and usually without declaration

The majority of drugs tested showed little or no displacing effect Most *antibiotics* (with the possible exception of some penicillin de rivatives) *antihistamines diuretics* and *general anaesthetics* so far investigated proved harmless All *drugs carrying a positive net charge* were found not to be displacing

Many drugs are given in small amounts, such as *hormones* some of the *synthetic diuretics digitoxin* etc and these will not displace bilirubin significantly even if they are bound strongly to the bilirubin site because the molar concentration available in the blood plasma is very small compared to that of albumin It is unnecessary to examine the displacing effect of such compounds

A certain reservation is necessary when applying these *in vitro* results to clinical practice Metabolites of drugs may displace more strongly than the compounds administered This has been found with sulfonamides (13), which are metabolized predominantly by $N(4)$ acetylation in the newborn infant Seven $N(4)$ acetylated sulfonamides have been tested and all these showed displacing effects equal to or stronger than those of the mother compounds A hydroxylated metabolite of phenylbutazone appears to be a very strong displacer (12) It would therefore be very useful if a test could be designed to assess the displacing effect of drugs in the human body Studies in Gunn rats (2 22 33) may also give suggestive results although it must be remembered that the pattern of drug metabolism and binding to albumin often shows species differences

Albumin therapy against bilirubin displacement

In the case of suspected bilirubin displacement whether caused by fatty acids by endogenous displacers or by competitive drugs a rational therapy is intravenous administration of albumin More binding sites are then provided for bilirubin as well as for the competitor and in case of exchange transfusion certain amounts of both substances are removed from the body

It should be noted that the plasma bilirubin concentration before treatment is likely to be low in these cases If 6 mol fatty acid is present per mol albumin a free bilirubin concentration of 50 nmol/l is reached when half of the albumin is occupied by bilirubin as seen from the diagram (Fig 5) Similar figures are obtained after sulfisoxazole in usual dosage (8) At usual levels of albumin this occurs at a bilirubin concentration about 200 to 250 μmol/l (12–15 mg/100 ml) and therapy is needed if the plasma bilirubin is above this The indication for treatment therefore can not be obtained by determination of plasma bilirubin alone and when displacers other than fatty acids are present also not by use of the diagram A method for quantitative determination of free bilirubin IX α(Z) in undiluted blood plasma would be helpful The result of this determination could be entered as the ordinate in the diagram (Fig 5) and would together with the plasma pH in the abscissa contribute rationally to the clinician s decision

ACKNOWLEDGEMENTS

OCULODENTODIGITAL DYSPLASIA SYNDROME

Report of Four Cases

C J THODÉN S RYÖPPY and P KUITUNEN

From the Children s Hospital University of Helsinki and Children s Castle Helsinki Finland

ABSTRACT Thoden C J Ryoppy S and Kuitunen P (Children s Hospital University of Helsinki and Children s Castle Helsinki Finland) Oculodentodigital dysplasia syndrome Report of four cases Acta Paediatr Scand 66 635 1977 —Four cases of oculodentodigital dysplasia are reported Three cases are from the same family father and two daughters These three cases have the characteristics typical of this disorder narrow nose hypoplastic alae nasi microphthalmia defects of the teeth syndactyly of the IV and V fingers and skeletal anomalies The fourth case differs from the earlier reported cases he has all the typical findings of oculodentodigital dysplasia but in addition he shows features not previously reported namely exceptionally poor vision mental retardation *monilethrix* and pili annuli changes of the hair

KEY WORDS Oculodentodigital syndrome

Lohman (8) was the first to describe a syndrome consisting of a typical face with hypoplastic alae nasi narrow nostrils microphthalmia microcornea anomalies of the iris and of syndactyly and camptodactyly of the fourth and fifth fingers and toes and enamel defects of the teeth Meyer Schwickerath et al (9) called the syndrome oculodentodigital dysplasia a name which later has been widely accepted in the literature Up to now 46 cases in 23 families have been published (1–16) Because no previous cases of oculodentodigital dysplasia have been reported from the Scandinavian countries we present here four cases which have been diagnosed at the Children s Hospital University of Helsinki and at the Children s Castle Helsinki Because of the similarities of signs and symptoms in cases 1 2 and 3 we report only cases 1 and 4 in more detail A summary of all four cases is given in Table 1

CASE REPORTS

Case 1 I T born 8 6 70 was studied at the age of four years She is a daughter of case 3 and the sister of case

There are no children in the family other than cases 1 and 2 (Fig 1a–c) The patient was born at term after an uneventful gestation with a birth weight of 3 300 g At the age of five months the girl was first seen at the Children s Hospital in Helsinki She had a peculiar face and nose the alae nasi were hypoplastic and the nostrils were narrow The patient had a high arched palate the eyes were small and the ears were prominent There was syndactyly of the fourth and fifth fingers on both hands The roentgenographs of the skull and the thorax were normal The ECG was normal as was the chromosomal analysis Ophthalmologic examination was performed at the age of four years The diameter of the cornea was 10 mm There were no anomalies of the iris or the lens According to the ophthalmologist the eye findings were normal The teeth were exceptionally worn and showed vertical streaks typical of amelogenesis imperfecta The X ray shadows of the primary teeth were faint the permanent teeth appeared normal The psychological examination revealed normal intelligence

Case 4 M R born 23 3 72 a boy was studied when two years old He is the oldest of three siblings The two younger siblings are healthy The patient was born at 38 weeks of gestation The birth weight was 3 740 g and

cidence of kernicterus among premature infants al lotted to two prophylactic antibacterial regimens *Pediatrics 18* 614 1956
41 Starinsky R & Shafrir E Displacement of albumin bound bilirubin by free fatty acids Implications for neonatal hyperbilirubinemia *Clin Chim Acta 29* 311 1970
42 Stern L Drug interactions Part II Drugs the new born infant and the binding of bilirubin to albumin *Pediatrics 49* 916 1972
43 Stern L Doray B Chan G & Schiff D Bili rubin metabolism and the induction of kernicterus *Birth Defects 12* No 2 255 1976
44 Thiessen H Jacobsen J & Brodersen R Dis placement of albumin bound bilirubin by fatty acids *Acta Paediatr Scand 61* 285 1972
45 Wennberg R Lau M & Rasmussen L F Clinical significance of unbound bilirubin *Pediatr Res 10* 434 1976

resent typical cases of oculodentodigital dysplasia which do not differ from cases reported elsewhere Case 4 with congenital blindness and retardation is an extremely severe variant of this syndrome All our patients have faces typical of oculodentodigital dysplasia a narrow nose and nostrils as well as hypoplastic alae nasi According to the literature the diameter of the cornea is between 6 and 10 5 mm (4 5 8 9 10 11 13 14) The corneal diameters of cases 1 2 3 and 4 were 10 8 5 9 and 8 mm The normal diameter of the adult cornea is said to be between 10 5 and 11 5 mm The retinal vessels of patient 4 were thread like—a finding not previously reported although a number of different eve anomalies have been observed (1 2 3) In a few reports it is stated that the patients had hypotrichosis or dry lusterless hair (4 5 6 7 9 14) which grew slowly In case 4 the anomaly of the hair could be exactly defined as a monilethrix change (alterations in the width of the hair) and as pili annuli (hair with spindle like air filled areas filling the whole marrow channel) Enamel defects of the teeth have been previously described (2 3 4 5 9 10 11 12 13 14) and were also found in our patients On the other hand our pediatric patients did not have broad mandibulae and alveolar ridges as has been reported in many cases (2 6 10 13) Our adult patient had broadening of the epiphyses of the long bones (4 7 13) and hyperostosis of the skull bones (13) In our two older children we could see only a slight broadening of the long bones The patients had the typical changes of the hands and feet (Table 1 Fig 3*a b* 1–15) Therapeutically little can be done except for the surgical correction of the syndactylies Because of the osseous anomalies this should be done early and even then a perfect result is not easily obtained The pa

[a] Aplasia of middle phal of finger V
[b] Monilethrix and pili annuli changes

the Apgar score was 7 At the age of two days the boy was admitted at the Children s Hospital in Helsinki On admission the typical findings of oculodentodigital dysplasia as described in case 1 were found (Fig 2) In the ophthalmologic examination microphthalmia and microcornea were seen The diameter of the cornea was 8 mm at the age of 1 5 years The fundi of the eyes showed greyish papillae the vessels were narrow and thread like the retinae were pale The patient had nystagmus and he possibly perceived light The lower incisors appeared at the age of seven months all teeth were yellow and there was an enamel defect Audiometry showed a 40–50 dB loss of hearing which might have been a result of frequent middle ear infections The hair was coarse and grew poorly under the microscope monilethrix as well as the changes of pili annuli were found Pneumoencephalography at the age of 4 5 months revealed a slight central atrophy EEG was repeatedly normal The ECG was abnormal there was a low QRS complex and the T waves were isoelectric or negative but the patient had no symptoms or signs of cardiac disease The cause of the ECG findings thus remains obscure The chromosomal analysis showed a normal karyotype Mental development was slow At the age of two years the patient reacted to some familiar phrases He would reach for some desirable toy which he would then transfer from one hand to the other

DISCUSSION

The four cases reported here are as far as we know the first cases to be reported from the Scandinavian countries Cases 1 2 and 3 rep

CASE REPORT

NEONATAL THYROTOXICOSIS

STEN PETERSEN and JØRGEN SERUP

From the Department of Paediatrics and the Department of Obstetrics and Gynaecology Central Hospital Nykøbing Falster Denmark

ABSTRACT Petersen S and Serup J (Department of Paediatrics and Department of Obstetrics and Gynaecology Central Hospital Nykøbing Falster Denmark) Neonatal thyrotoxicosis Acta Paediatr Scand 66 639 1977.—Neonatal thyrotoxicosis is a transient hyperthyroidism in infants of mothers with current or previous thyrotoxicosis The pathogenesis has been accepted to be placental transfer of maternal thyroid stimulating immunoglobulins Of two siblings from a previous thyrotoxic mother the first had marked symptoms of thyrotoxicosis but during the second pregnancy antithyroid treatment was given to the mother and though the child had high levels of thyroid hormones for 6 weeks it had only minimal symptoms of thyrotoxicosis

KEY WORDS Hyperthyroidism newborn long acting thyroid stimulator human thyroid stimulating immunoglobulin

A transient hyperthyroid condition may be seen in newborn infants of mothers with previous or current thyrotoxicosis Cardiac failure is responsible for a lethality of about 16% in the previously reported cases (6) Placental transfer of long acting thyroid stimulator (LATS) is considered responsible for a number of cases but recently another immunoglobulin human thyroid stimulating immunoglobulin (HTSI) has been detected in some cases Antithyroid treatment of the mother during pregnancy is important in preventing serious disease in the newborn This is a report of 2 siblings who demonstrated a striking difference between the untreated and treated course of the disease

METHODS

Total serum thyroxine concentration (T) was assayed using the Thyopac® 5 kit from The Radiochemical Centre Amersham England Normal ranges were 65–145 nmol/l in adults and 65–175 nmol/l in pregnant women

Free thyroxine (FT_4) was assayed as normalized thyroxine ratio by the same Thyopac® 5 kit Normal ranges in adults and in pregnant women were 0 88–1 11 relative units

Serum tri iodothyronine (T_3) was assayed using The Radiochemical Centre s T_3 RIA kit Normal ranges were 1 3–3 5 nmol/l in adults and 1 5–5 0 nmol/l in pregnant women

Long acting thyroid stimulator (LATS) was assayed using white guinea pigs (4) In this technique LATS levels below 1 25 rel U were normal 1 25–1 50 was suspected elevated and more than 1 50 was considered significant pathologic

CASE REPORTS

The mother had exophthalmic hyperthyroidism at the age of 17 years She had undergone partial thyroidectomy and had since been clinically euthyroid without further treatment A mild exophthalmos remained Non pregnant laboratory data T_4 155 nmol/l and FT_4 1 13 rel U

Case 1

Her first child a girl was delivered 7½ years after the thyroidectomy by a Caesarean section at 34 weeks gestation because of prolapsed umbilical cord Birth weight was 2050 g and Apgar score 10 She was dysmature with a slight exophthalmos and thyroid enlargement The in

tients with oculodentodigital dysplasia have usually been of normal intelligence only a few slightly retarded patients (14) have been reported In this respect case 4 represents an exception with slow intellectual and physical development This could be either explained as a very severe case of oculodentodigital dysplasia or the patient could have suffered from an intrauterine or a perinatal injury The reason for the central atrophy found in the pneumoencephalogram cannot be explained satisfactorily with the available facts Our patients represent both types of inheritance known to occur in oculodentodigital dysplasia (13) Cases 1–3 seem to be dominantly inherited, case 4 represents the sporadically occurring type of oculodentodigital dysplasia

In cord blood T_4 was [illegible] nmol/l and FT was [illegible] rel U T_3 from 2–4 weeks was more than 9 nmol/l and at 5 weeks it decreased to 7 7 nmol/l LATS in cord blood was 0 81 rel U at 4 weeks it was 0 97 rel U and at 6 weeks it was [illegible] rel U Chest X ray was normal and bone age at 3 months was 1 year 3 months

DISCUSSION

White (13) presented in 1912 the first description of neonatal thyrotoxicosis In 1958 Adams (1) detected the long acting thyroid stimulator (LATS) and when McKenzie (7) in 1964 presented five cases of neonatal thyrotoxicosis in which LATS was present in mother and child it seemed reasonable to believe that LATS which is an immunoglobulin G and is able to pass the placenta was responsible for the disease in the newborn Several cases in which LATS was detected have been published but in some recent cases it was impossible to determine LATS in the mothers and in the children (14) In 1974 Nutt et al (9) presented a case in which no LATS was found They found another immunoglobulin LATS protector (LATS P) later called human thyroid stimulating immunoglobulin (HTSI) in mother and child The importance of HTSI in LATS negative cases of neonatal thyrotoxicosis has been confirmed by Dirmikis & Munro (2) and Mitchell et al (8)

Thyrotoxic symptoms in the newborn appear within the first week of life but in cases where the mother has been treated during pregnancy the symptoms may be vague delayed or fail to appear Preterm birth restlessness low weight gain diarrhoea tachycardia thyroid enlargement and exophthalmos are common findings Cardiac failure is a frequent and serious complication Accelerated bone maturity is common Rare findings are thymic enlargement and idiopathic thrombocytopenic purpura (6) The disappearance of the symptoms has been related to the elimination of the passively transferred thyroid stimulating immunoglobulins

From about 20 weeks gestation the endocrine regulatory function of the foetus is fully developed From this time it may be possible for the thyroid stimulating immunoglobulins to produce intrauterine thyrotoxicosis which may appear with foetal tachycardia and active movements Antithyroid therapy should be given to the mother from this time to render the foetus euthyroid and to reduce the risk of preterm birth The treatment will clearly reduce the severity of thyrotoxicosis in the newborn This can be due to reduction of the immunoglobulin level (4) but it can also be an effect of placentally transferred antithyroid drugs

The different clinical symptoms in our 2 siblings the first untreated and the second treated during pregnancy confirms the effect of this treatment The laboratory findings were almost identical in the two infants and it is unclear why case 2 was not clinically thyrotoxic This may be a result of the peripheral effect of transplacental transferred propylthiouracil which blocks the extrathyroid conversion of T_4 to the biologically more active T_3 (5)

To prevent neonatal hyperthyroidism treatment should be given to the mother during pregnancy and in case of previous or current thyrotoxicosis of the mother investigation for LATS and HTSI is important in predicting neonatal thyrotoxicosis

If a newborn becomes thyrotoxic the treat

Fig 1 Case 1 Exophthalmos 3 weeks old

fant was restless and had diarrhoea During the second week of life exophthalmos (Fig 1) thyroid enlargement (Fig 2) and hyperactivity progressed Heart rate was 180–200 per min but there was no heart murmur or enlarged liver She was treated with phenobarbital and supplementary oxygen in an incubator From the age of 4 weeks the symptoms subsided and from 6 weeks regression in exophthalmos and thyroid enlargement was observed The weight gain was slow for the first 8 weeks

The T_4 and FT_4 levels are seen in Fig 3 The T_3 level was 6 5 nmol/l at 6 weeks and 1 6 nmol/l at 12 weeks Quantitative estimation of LATS was not available for us at that time but qualitatively some LATS activity was detected at 5 weeks in mother and infant Chest X ray showed extreme thymic enlargement At 3 months the bone age according to Greulich & Pyle was 1½–2 years There was no signs of cranial synostosis At 2½ years of age the development was normal She was euthyroid with normal T_4 and FT_4

Case 2

During her second pregnancy 2½ years after the first the mother was without any clinical signs of hyperthyroidism At 18 weeks gestation her T_4 was 264 nmol/l FT_4 1 22 rel U and T_3 7 0 nmol/l At 26 weeks gestation the foetal heart rate increased from 140 to 165 per min and the foetal movements were more active This was regarded as symptoms of foetal thyrotoxicosis and the mother was given antithyroid treatment with propylthiouracil 300 mg per day for 2 weeks and the dose was gradually decreased to a daily dose of 62 5 mg at 32 weeks gestation During treatment T_4 decreased to 130 nmol/l FT_4 to 0 95 rel U and T_3 to 5 9 nmol/l The foetal movements and heart rate returned to normal Propylthiouracil in a daily dose of 62 5 mg was continued until the day of delivery and the T_4 and FT_4 remained within normal limits The LATS investigation showed at 18 weeks 0 87 rel U at 26 weeks 1 56 rel U and at 34 weeks 0 76 rel U

The child a boy was born spontaneously at 37 weeks gestation He was asphyxiated with Apgar score 5 after 1 min and 10 after 10 min Birth weight was 2 500 g During the first day of life he was treated with supplementary oxygen in an incubator because of mild respiratory distress There was no exophthalmos or thyroid enlargement He was trembling somewhat during the first 3 days and was treated with phenobarbital The heart rate was 160 The weight gain was slow for the first 3 weeks probably because of maternal hypogalactia but after supplementary feeding with evaporated milk products he was gaining weight properly Though the levels of thyroid hormones were almost as high as in case 1 (Fig 3) and much exceeded the physiological increased levels in the neonatal period (10) he never showed clinical symptoms of thyrotoxicosis except a slight lid retraction

Fig 2 Case 1 Thyroid enlargement 4 weeks old

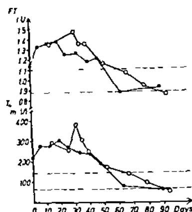

Fig 3 Serum thyroxine (T) and free thyroxine (FT) levels in case 1 O—O and case 2 ●—● Normal range in adults = = =

In cord blood T was 2 1 nmol/l and FT_4 was 1 14 rel U T from 2–4 weeks was more than 9 nmol/l and at 5 weeks it decreased to 7 7 nmol/l LATS in cord blood was 0 81 rel U at 4 weeks it was 0 97 rel U and at 6 weeks it was 0 3? rel U Chest X ray was normal and bone age at 3 months was 1 year 3 months

DISCUSSION

White (13) presented in 1912 the first description of neonatal thyrotoxicosis In 1958 Adams (1) detected the long acting thyroid stimulator (LATS) and when McKenzie (7) in 1964 presented five cases of neonatal thyrotoxicosis in which LATS was present in mother and child it seemed reasonable to believe that LATS which is an immunoglobulin G and is able to pass the placenta was responsible for the disease in the newborn Several cases in which LATS was detected have been published but in some recent cases it was impossible to determine LATS in the mothers and in the children (14) In 1974 Nutt et al (9) presented a case in which no LATS was found They found another immunoglobulin LATS protector (LATS P) later called human thyroid stimulating immunoglobulin (HTSI) in mother and child The importance of HTSI in LATS negative cases of neonatal thyrotoxicosis has been confirmed by Dirmikis & Munro (2) and Mitchell et al (8)

Thyrotoxic symptoms in the newborn appear within the first week of life but in cases where the mother has been treated during pregnancy the symptoms may be vague delayed or fail to appear Preterm birth restlessness low weight gain diarrhoea tachycardia thyroid enlargement and exophthalmos are common findings Cardiac failure is a frequent and serious complication Accelerated bone maturity is common Rare findings are thymic enlargement and idiopathic thrombocytopenic purpura (6) The disappearance of the symptoms has been related to the elimination of the passively transferred thyroid stimulating immunoglobulins

From about 20 weeks gestation the endocrine regulatory function of the foetus is fully developed From this time it may be possible for the thyroid stimulating immunoglobulins to produce intrauterine thyrotoxicosis which may appear with foetal tachycardia and active movements Antithyroid therapy should be given to the mother from this time to render the foetus euthyroid and to reduce the risk of preterm birth The treatment will clearly reduce the severity of thyrotoxicosis in the newborn This can be due to reduction of the immunoglobulin level (4) but it can also be an effect of placentally transferred antithyroid drugs

The different clinical symptoms in our 2 siblings the first untreated and the second treated during pregnancy confirms the effect of this treatment The laboratory findings were almost identical in the two infants and it is unclear why case 2 was not clinically thyrotoxic This may be a result of the peripheral effect of transplacental transferred propylthiouracil which blocks the extrathyroid conversion of T_4 to the biologically more active T_3 (5)

To prevent neonatal hyperthyroidism treatment should be given to the mother during pregnancy and in case of previous or current thyrotoxicosis of the mother investigation for LATS and HTSI is important in predicting neonatal thyrotoxicosis

If a newborn becomes thyrotoxic the treat

ment recommended is symptomatically pheno barbital and digoxin and antithyroid treatment with propylthiouracil and iodides (3) Propranolol is reported very effective (12)

The obstetric details of our cases are described elsewhere (11)

CASE REPORT

A CASE OF APPARENT HYPOPITUITARISM COMPLICATING CHRONIC INFLAMMATORY BOWEL DISEASE IN CHILDHOOD AND ADOLESCENCE

J R B GREEN D P O DONOGHUE C R W EDWARDS and A M DAWSON

From the Departments of Gastroenterology and Medicine St Bartholomew s Hospital London England

ABSTRACT Green J R B O Donoghue D P Edwards C R W and Dawson A M (Departments of Gastroenterology and Medicine St Bartholomew s Hospital London England) A case of apparent hypopituitarism complicating chronic inflammatory bowel disease in childhood and adolescence Acta Paediatr Scand 66 643 1977.—There is conflicting evidence regarding the adequacy of hypothalamic pituitary function in children and adolescents with chronic inflammatory bowel disease complicated by growth retardation and delayed sexual maturation A child with Crohn s disease who has never received corticosteroid therapy had delay of both growth and sexual maturation and has been investigated over the course of his disease In addition to a skull X ray (normal) and thyroid function tests (normal) a standard insulin tolerance test (insulin 0 15 u/kg) and a standard gonadotrophin releasing hormone (Gn RH) test (100 μg Gn RH i/v) were performed when the bowel disease was in relapse and again during a remission of the bowel disease achieved by surgery When the bowel disease was in relapse (coincident with growth arrest) results showed an inadequate release of gonadotrophins and of growth hormone (even after pre treatment with stilboestrol) but normal release of cortisol and prolactin During a remission of the bowel disease coinciding with a period of rapid catch up growth release of growth hormone was normal and that of gonadotrophins supranormal The demonstration of a reversible apparent partial hypopituitarism in this boy not only re-questions the adequacy of hypothalamic pituitary function in inflammatory bowel disease but also indicates a potential diagnostic pitfall in the routine investigation of growth retardation if gastrointestinal symptoms are not prominent at presentation

KEY WORDS Crohn s disease growth retardation growth hormone partial hypopituitarism

Delayed skeletal growth and sexual maturation are recognised complications of chronic inflammatory bowel disease occurring in childhood or adolescence (1 7 15) If gastrointestinal symptoms are prominent at presentation the cause of the growth stunting may be obvious However difficulty in diagnosis may arise in cases where delayed maturation precedes gastrointestinal symptoms (13)

The pathogenesis of growth retardation in inflammatory bowel disease remains uncertain Previous studies have shown either impaired (8) or normal (3) stimulated growth hormone release in severely growth retarded children and adolescents with inflammatory bowel disease The latter finding of normal growth hormone release in these patients has subsequently been the more widely accepted

In view of this conflicting evidence the results of this detailed study of a boy with

ment recommended is symptomatically phenobarbital and digoxin and antithyroid treatment with propylthiouracil and iodides (3) Propranolol is reported very effective (12)

The obstetric details of our cases are described elsewhere (11)

CASE REPORT

A CASE OF APPARENT HYPOPITUITARISM COMPLICATING CHRONIC INFLAMMATORY BOWEL DISEASE IN CHILDHOOD AND ADOLESCENCE

J R B GREEN D P O DONOGHUE C R W EDWARDS and A M DAWSON

From the Departments of Gastroenterology and Medicine St Bartholomew s Hospital London England

ABSTRACT Green J R B O Donoghue D P Edwards C R W and Dawson A M (Departments of Gastroenterology and Medicine St Bartholomew s Hospital London England) A case of apparent hypopituitarism complicating chronic inflammatory bowel disease in childhood and adolescence Acta Paediatr Scand 66 643 1977 —There is conflicting evidence regarding the adequacy of hypothalamic pituitary function in children and adolescents with chronic inflammatory bowel disease complicated by growth retardation and delayed sexual maturation A child with Crohn s disease who has never received corticosteroid therapy had delay of both growth and sexual maturation and has been investigated over the course of his disease In addition to a skull X ray (normal) and thyroid function tests (normal) a standard insulin tolerance test (insulin 0 15 u/kg) and a standard gonadotrophin releasing hormone (Gn RH) test (100 μg Gn RH i/v) were performed when the bowel disease was in relapse and again during a remission of the bowel disease achieved by surgery When the bowel disease was in relapse (coincident with growth arrest) results showed an inadequate release of gonadotrophins and of growth hormone (even after pre treatment with stilboestrol) but normal release of cortisol and prolactin During a remission of the bowel disease coinciding with a period of rapid catch up growth release of growth hormone was normal and that of gonadotrophins supranormal The demonstration of a reversible apparent partial hypopituitarism in this boy not only re-questions the adequacy of hypothalamic pituitary function in inflammatory bowel disease but also indicates a potential diagnostic pitfall in the routine investigation of growth retardation if gastrointestinal symptoms are not prominent at presentation

KEY WORDS Crohn s disease growth retardation growth hormone partial hypopituitarism

Delayed skeletal growth and sexual maturation are recognised complications of chronic inflammatory bowel disease occurring in childhood or adolescence (1 7 15) If gastrointestinal symptoms are prominent at presentation the cause of the growth stunting may be obvious However difficulty in diagnosis may arise in cases where delayed maturation precedes gastrointestinal symptoms (13)

The pathogenesis of growth retardation in inflammatory bowel disease remains uncertain Previous studies have shown either impaired (8) or normal (3) stimulated growth hormone release in severely growth retarded children and adolescents with inflammatory bowel disease The latter finding of normal growth hormone release in these patients has subsequently been the more widely accepted

In view of this conflicting evidence the results of this detailed study of a boy with

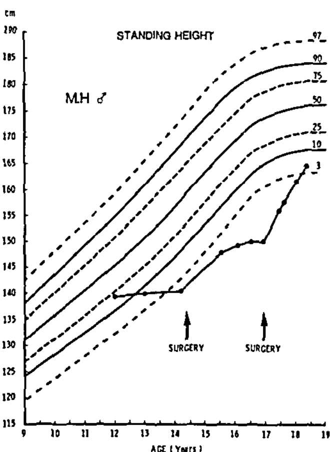

Fig 1 Standing height record of M H between the ages of *11 5* years and *18* years Arrows indicate the timing of the two laparotomies (Chart from Tanner 1958 [14])

Crohn s disease and severe growth retardation have two implications firstly they re open the question of the adequacy of growth hormone release in this condition and secondly they *demonstrate a potential diagnostic pitfall in the* routine investigation of growth retardation

CASE HISTORY

This boy first presented at the referring hospital when 12 years old with a nine month history of morning nausea occasional vomiting and intermittent colicky upper abdominal pain Physical examination was normal and he was just below the 25th percentile for both height and weight Investigations including a barium meal and follow through examination were normal A diagnosis of periodic syndrome was made and a low milk low fat diet was prescribed initially with improvement of his symptoms

Two years later when aged 14 2 years he was again referred to the same hospital with an eighteen month history of recurrent intermittent upper abdominal colicky pain occasional vomiting and failure to grow Physical examination was again normal except that he was now below the 3rd percentile for height and weight Barium follow through examination now showed extensive small bowel abnormalities consistent with Crohn s disease At subsequent laparotomy 150 cm of involved ileum and jejunum were resected Histology confirmed Crohn s disease and the patient made a satisfactory post-operative recovery on no treatment He remained symptom free for just one year and his height increased by 7 cm although he still remained below the 3rd percentile (Fig 1)

At age 15 5 years he developed a recurrence of nausea colicky upper abdominal pain and episodic abdominal distension Barium follow through examination showed changes of recurrent Crohn s disease particularly affecting the jejunum Eventually after a trial of salazopyrine the patient was referred for further management

He was first admitted to this hospital for investigation at the age of 16 9 years At that time he continued to complain of the same abdominal symptoms but had no diarrhoea Abdominal examination sigmoidoscopy and rectal biopsy were all normal as was the barium enema examination His height was now well below the 3rd percentile (as was his weight) and he was between stages 3 and 4 for both pubic hair and genital development with testes of 12 and 15 ml sparse axillary hair and slight voice deepening Skull X rays were normal and bone age was 13 1 years Thyroid function was normal with a free thyroxine index of 5 9 (normal range 4 5–13 5) Plasma gonadotrophins after 100 μg of intravenous gonadotrophin releasing hormone (Gn RH) showed an impaired pubertal type of response (10) (Table 1) After intravenous soluble insulin (0 15 u/kg) adequate hypoglycaemia was obtained but the plasma growth hormone response was impaired (4) (Table 2) This was not improved by two days of pretreatment with stilboestrol 1 mg tds (2 6) (Table 2) Plasma cortisol response (717 nmol/l) and plasma prolactin response (15 μg/l) to hypoglycaemia were normal (Table 2)

At subsequent laparotomy a further 90 cm of jejunum was removed and post-operatively the patient was started on azathioprine (2 mg/kg) Six months post-operatively with symptoms in full remission the fasting plasma growth hormone was much higher than on both previous occasions and values of over 20 μg/l were recorded after adequate hypoglycaemic stimulus (Table 2) the accepted criterion of a normal response (4) Basal gonadotrophin

Table 1 *Gonadotrophin releasing hormone (Gn RH) tests in relapse and remission (M H)*

concentrations were now elevated with an exaggerated response to Gn RH (Table 1) One year post-operatively aged 18 years he remains asymptomatic He is now sexu ally mature and his height (164 cm) is approaching the tenth percentile (Fig 1) His bone age (16 5 years) more nearly matches his chronological age

The patient has never received corticosteroid therapy at any stage of his illness

DISCUSSION

There are few studies of growth hormone sta tus in children and adolescents with inflamma tory bowel disease complicated by delayed growth and sexual maturation In the largest single study McCaffery et al (8) reported that 11 of 13 severely growth retarded children with inflammatory bowel disease failed to achieve adequate plasma growth hormone concentrations after hypoglycaemic stimulus This study could be criticised however in that all but two patients had previously re ceived significant corticosteroid therapy and repeat stimulation after stilboestrol pre treat ment was not performed Furthermore there was no indication of whether or not growth hormone responses returned to normal after a remission of the bowel disease had been achieved In contrast Gotlin & Dubois (3) found normal nyctohemeral plasma growth hormone concentrations and normal plasma growth hormone response after arginine in fusion in 6 severely growth retarded adoles cents with inflammatory bowel disease This together with the objections to the previous study has led to the prevalent view that growth hormone release is not impaired in pa tients with growth retardation and inflamma tory bowel disease In view of this conflict of evidence the patient we report here provided a rare opportunity for endocrinological study as he has never received corticosteroid therapy

The present study shows that when the pa tient s disease was in relapse his stimulated growth hormone release was inadequate even after stilboestrol pre treatment Impaired growth hormone release may occasionally be found in some normal subjects undergoing puberty but pre treatment with stilboestrol is found to correct this to normal (2 6) In contrast when he was in clinical remission both fasting plasma growth hormone concen tration and the response to hypoglycaemia were well within normal limits A parallel change was seen in the plasma gonadotrophin response to Gn RH The cause of the exag gerated response to Gn RH found during a re mission of the bowel disease is uncertain it may relate either to a de suppression effect associated with remission of the bowel disease or possibly may be due to therapy with aza thioprine at the time of re testing In contrast both plasma cortisol and plasma prolactin re sponses to hypoglycaemia remained normal throughout

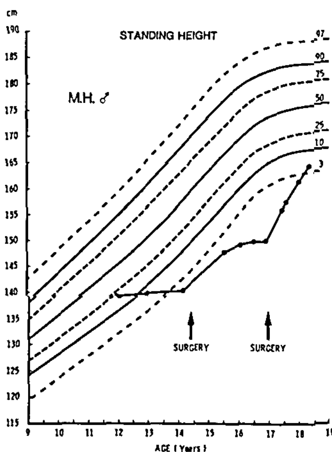

Fig 1 Standing height record of M H between the ages of 11 5 years and 18 years Arrows indicate the timing of the two laparotomies (Chart from Tanner 1958 [14])

Crohn s disease and severe growth retardation have two implications firstly they re open the question of the adequacy of growth hormone release in this condition and secondly they demonstrate a potential diagnostic pitfall in the routine investigation of growth retardation

concentrations were now elevated with an exaggerated response to Gn RH (Table 1) One year post-operatively aged 18 years he remains asymptomatic He is now sexually mature and his height (164 cm) is approaching the tenth percentile (Fig 1) His bone age (16 5 years) more nearly matches his chronological age

The patient has never received corticosteroid therapy at any stage of his illness

DISCUSSION

There are few studies of growth hormone status in children and adolescents with inflammatory bowel disease complicated by delayed growth and sexual maturation In the largest single study McCaffery et al (8) reported that 11 of 13 severely growth retarded children with inflammatory bowel disease failed to achieve adequate plasma growth hormone concentrations after hypoglycaemic stimulus This study could be criticised however in that all but two patients had previously received significant corticosteroid therapy and repeat stimulation after stilboestrol pre treatment was not performed Furthermore there was no indication of whether or not growth hormone responses returned to normal after a remission of the bowel disease had been achieved In contrast Gotlin & Dubois (3) found normal nyctohemeral plasma growth hormone concentrations and normal plasma growth hormone response after arginine infusion in 6 severely growth retarded adolescents with inflammatory bowel disease This together with the objections to the previous study has led to the prevalent view that growth hormone release is not impaired in patients with growth retardation and inflammatory bowel disease In view of this conflict of evidence the patient we report here provided a rare opportunity for endocrinological study as he has never received corticosteroid therapy

The present study shows that when the patient s disease was in relapse his stimulated growth hormone release was inadequate even after stilboestrol pre treatment Impaired growth hormone release may occasionally be found in some normal subjects undergoing puberty but pre treatment with stilboestrol is found to correct this to normal (2 6) In contrast when he was in clinical remission both fasting plasma growth hormone concentration and the response to hypoglycaemia were well within normal limits A parallel change was seen in the plasma *gonadotrophin* response to Gn RH The cause of the exaggerated response to Gn RH found during a remission of the bowel disease is *uncertain it* may relate either to a de suppression effect associated with remission of the bowel disease or possibly may be due to therapy with azathioprine at the time of re testing In contrast both plasma cortisol and plasma prolactin responses to hypoglycaemia *remained* normal throughout

The conclusion from these investigations is that, when clinical disease was in relapse the pattern of endocrine findings was indistinguishable from that seen in partial hypopituitarism These abnormalities were transient because they disappeared when the bowel disease was in remission Findings similar to these have been reported in growth retardation due to coeliac disease (16) and severe emotional deprivation (12)

It is difficult to reconcile the results of this boy with the normal arginine provocation test results of Gotlin & Dubois (3) In view of this conflict caution should perhaps be exercised before excluding the possibility of an abnormality of growth hormone release in this condition as the differential response of the pituitary to the two stimuli may indicate a more subtle disturbance of function Whatever the role of pituitary growth hormone release in this condition, there may also be an additional element of end organ resistance to growth hormone as McCaffery and colleagues (9) have shown in a small and rather unsatisfactory study that administration of human growth hormone to three stunted patients with inflammatory bowel disease produced no dramatic increase in height

Malnutrition from a combination of anorexia malabsorption and increased enteric protein loss no doubt contributes directly to the growth retardation of patients with inflammatory bowel disease However prolonged parenteral nutrition (without surgery) has been found to lead only to a partial restoration of linear height (5) so nutritional status is therefore only one of probably many factors in the retardation of growth That malnutrition might be more directly responsible for the growth hormone abnormalities demonstrated in this boy seems unlikely since children with gross protein–calorie malnutrition (marasmus) and growth retardation have very high basal plasma growth hormone concentrations (11)

In conclusion this boy with Crohn s disease and growth retardation had an impairment of stimulated pituitary release of both plasma growth hormone and plasma gonadotrophins when the bowel disease was in relapse These apparent defects disappeared after a remission of the Crohn s disease had been achieved by surgery These results therefore re question the normality of pituitary function previously accepted in such patients Furthermore since both insulin induced hypoglycaemia and the Gn RH test are widely used in the routine investigation of growth retardation these results demonstrate how patients with occult inflammatory bowel disease may be wrongly diagnosed as having partial hypopituitarism unless the possibility of underlying inflammatory bowel disease is specifically considered

CASE REPORT

ANEURYSM OF THE NONPATENT DUCTUS ARTERIOSUS IN THE NEWBORN

M RUTISHAUSER G RONEN and F WYLER

From the Department of Paediatrics University of Basel Basel Switzerland

ABSTRACT Rutishauser M Ronen G and Wyler F (Department of Paediatrics University Children s hospital Basel Switzerland) Aneurysm of the nonpatent ductus arteriosus in the newborn Acta Paediatr Scand 66 649 1977.—Aneurysm of the nonpatent ductus arteriosus in the newborn is a rare but potentially fatal condition Of reported ductal aneurysm up to 1969 diagnosis was made at autopsy only We report here to our knowledge for the first time on a two week old infant with correct preoperative angiographic diagnosis followed by a successful surgical cure

KEY WORDS Infantile ductal aneurysm

An aneurysm of the ductus arteriosus in the neonate in contrast to simple patency is very rare From the 60 cases reported in the literature (2 3 4 5 6 7) it seems that in no instance a correct preoperative diagnosis was followed by a successful surgical cure as was the case in our 2 weeks old infant

CASE REPORT

The 3980 g male newborn offspring of a 26-year-old I para showed radiological cardiomegaly together with a transient hypoglycemia (20 mg/100 ml) on the first day of life On the 5th day suddenly heart failure developed There was tachycardia (160/min) tachypnoe (100/min) and an enlarged liver 6 cm below the costal margin There were normal heart sounds and no murmurs The ECG showed an axis of +100° and no signs of hypertrophy The chest X ray (Fig 1) revealed a slight cardiomegaly and distinct round shadow in the upper left mediastinal region The baby was treated with digoxin and diuretics improved with this therapy and was catheterized 2 days later The saturations and pressures in both heart sides were normal On cineangiography from the left ventricle the only anomaly was a big aneurysm at the aortic end of the already closed ductus arteriosus (Fig)

The child continued to improve and on day 10 the signs of heart failure were virtually gone It was apparent that the congestive heart failure was not related to the ductal aneurysm but was possibly connected with hypoglycemia and cardiomegaly of infants of diabetic mothers Since rupture and thrombo-embolism of the ductal aneurysm were reported as dangerous complications (? 3 4) surgical removal was performed on the 14th day The size of this aneurysmal structure was 13×20 mm Its wall was thin and fragile and was in communication only with the descending aorta The pulmonary end was already a narrow string of connective tissue Histologically there was a fresh necrosis of the media of the ductus arteriosus The postoperative course was uneventful digoxin was discontinued a week later and a healthy child was discharged

COMMENT

Under normal circumstances the ductus arteriosus constricts shortly after birth and anatomical closure is completed within 5–7 days but may not occur up till 21 days Constriction and subsequent intimal fibrosis is observed initially at the pulmonary end then the closure extends also to the aortic site The wall of the ductus undergoes changes by a de

crease in elastic fibres and by increase of fibrous connective tissue giving rise to the ligamentum arteriosum The aortic end of the ductus the ductal ampulla (ductal bump) may be seen roentgenologically and angiographically in many newborns for 1–4 days (1) If closure of the aortic end is delayed the ductus in effect becomes an aortic diverticulum In our case this formation might have been related to heart failure since hypoxia from low cardiac output could have interfered with physiological involution This diverticulum is under systemic pressure and along with the involution of the ductal tissue dilatation and aneurysm formation could be postulated Histologically the smooth muscle of the resected specimen in our case was necrotic whereas the other layers were normal Similar anatomical findings were reported in the literature (2 3 4) Although spontaneous uncomplicated involutions were described (6) rupture dissection thromboembolic complications and infections of the aneurysm were shown to account for a very high mortality (2 3 4) Thus up to 1969 the reported cases of ductal aneurysms in infancy were all diagnosed at autopsy The only infant where this malformation was recognized angiographically died shortly after the investigation (7) Two infants age 4 weeks and 12 days respectively were successfully operated but the indication for surgery was an intrathoracic mass of unknown origin (5)

Fig 2 Angiography from the left ventricle showing a big aneurysm at the aortic end of the ductus arteriosus

From our experience and from the reviewed literature (2 3 4 5 6 7) the following conclusions can be drawn Specific clinical symptoms are absent Roentgenographic examination is not diagnostic but a tumor like left sided mediastinal mass in the newborn is possibly an aneurysm of the ductus arteriosus Because no further involution can be expected but life threatening complications are the rule angiographical confirmation of the ductal aneurysm and prompt surgical removal are pertinent

CASE REPORT

THE LARSFN SYNDROME AND GLIAL PROLIFERATION IN THE BRAIN

PER HENRIKSSON STEN IVARSSON and GEORG THEANDER

From the Department of Paediatrics and the Department of Radiology (Paediatric Division) University of Lund Allmanna Sjukhuset Malmo Sweden

ABSTRACT Henriksson P Ivarsson S and Theander G (Department of Paediatrics and Department of Radiology (Paediatric Division) University of Lund Malmo General Hospital Malmo Sweden) The Larsen syndrome and glial proliferation in the brain Acta Paediatr Scand 66 653 1977.—A case of the Larsen syndrome is reported in which postmortem examination of the brain revealed glial proliferation resembling tuberous sclerosis The differential diagnosis of the syndrome and the possible significance of the lesions are discussed

KEY WORDS Larsen syndrome congenital knee dislocation glial proliferation tuberous sclerosis

In 1950 Larsen et al (3) described 6 cases of a new syndrome characterised by congenital dislocation of multiple joints and a typical facies The joints affected differed from one case to the other but all the patients had dislocated knees and malformed feet and most of them also dislocated hips and elbows The facial characteristics were a prominent forehead hypertelorism and a depressed nasal bridge causing a flattened appearance of the face Several further abnormalities found in some of these cases or of those later diagnosed as the Larsen syndrome are considered inconstant components in the malformation complex Some of them such as supernumerary carpal bones do not become evident until several years after birth The etiology and pathogenesis of the syndrome are unknown

In 1972 Silverman (8) reported 5 personal cases of the Larsen syndrome and reviewed 41 which he had culled from the literature most of them had been published under various other diagnoses The same year Steel & Kohl (10) reported 3 siblings with the syndrome Several examples without specified sources were collected by Spranger et al (9) in their atlas of bone dysplasias Since then 5 cases have been reported by Payet (4) 3 by Robertson et al (7) and one by Swensson et al (11) The present paper adds one case in which unexpected lesions were found in the brain

CASE HISTORY

The patient was a newborn girl with no family history of bone disease or dysplasia Her mother aged 28 had 2 years previously had a spontaneous abortion preceded by two legal abortions The girl was born in the 36th week of gestation (vaginal delivery) after premature rupture of the membranes An excess of amniotic fluid was noted The placenta and umbilical cord were normal There was no history of exposure to drugs or ionising radiation during pregnancy

The girl weighed 2 100 g at birth She was moderately asphyctic and had biparietal cephalhematomas The skull was relatively large with a slightly prominent forehead low hairline a flat nasal bridge and eyes somewhat wide apart (Fig 1) Both knees were dislocated and markedly unstable There was a simian crease in the right hand and

ABSTRACT Henriksson P Ivarsson S and Theander G (Department of Paediatrics and Department of Radiology (Paediatric Division) University of Lund Malmo General Hospital Malmo Sweden) The Larsen syndrome and glial proliferation in the brain Acta Paediatr Scand 66 653 1977.—A case of the Larsen syndrome is reported in which postmortem examination of the brain revealed glial proliferation resembling tuberous sclerosis The differential diagnosis of the syndrome and the possible significance of the lesions are discussed

KEY WORDS Larsen syndrome congenital knee dislocation glial proliferation tuberous sclerosis

In 1950 Larsen et al (3) described 6 cases of a new syndrome characterised by congenital dislocation of multiple joints and a typical facies The joints affected differed from one case to the other but all the patients had dislocated knees and malformed feet and most of them also dislocated hips and elbows The facial characteristics were a prominent forehead hypertelorism and a depressed nasal bridge causing a flattened appearance of the face Several further abnormalities found in some of these cases or of those later diagnosed as the Larsen syndrome are considered inconstant components in the malformation complex Some of them such as supernumerary carpal bones do not become evident until several years after birth The etiology and pathogenesis of the syndrome are unknown

In 1972 Silverman (8) reported 5 personal cases of the Larsen syndrome and reviewed 41 which he had culled from the literature most of them had been published under various other diagnoses The same year Steel & Kohl (10) reported 3 siblings with the syndrome Several examples without specified sources were collected by Spranger et al (9) in their atlas of bone dysplasias Since then 5 cases have been reported by Payet (4) 3 by Robertson et al (7) and one by Swensson et al (11) The present paper adds one case in which unexpected lesions were found in the brain

CASE HISTORY

The patient was a newborn girl with no family history of bone disease or dysplasia Her mother aged 28 had 2 years previously had a spontaneous abortion preceded by two legal abortions The girl was born in the 36th week of gestation (vaginal delivery) after premature rupture of the membranes An excess of amniotic fluid was noted The placenta and umbilical cord were normal There was no history of exposure to drugs or ionising radiation during pregnancy

The girl weighed 100 g at birth She was moderately asphyctic and had biparietal cephalhematomas The skull was relatively large with a slightly prominent forehead low hairline a flat nasal bridge and eyes somewhat wide apart (Fig 1) Both knees were dislocated and markedly unstable There was a simian crease in the right hand and

Fig 1 Facial appearance at 5 days of age

deformities of the feet Auscultation revealed an abnormal second heart sound but no definite murmur The general condition of the baby rapidly deteriorated and she died after 13 days the main clinical symptoms having been those of cardiac failure

Radiologic findings

The chest and abdomen and the entire skeleton were radiologically examined on the 12th day of life The heart was considerably larger than normal and the pulmonary vasculature suggested a left to right shunt The skull was normal except for the parietal cephalhematomas and slight bossing of the frontal bone None of the tubular bones had ossification centres in their epiphyses and the pubic bones were unossified A thin layer of undermineralised bone was seen along all metaphyseal surfaces and at the periphery of the pelvic and tarsal bones There was a bilateral metatarsus deformity and both knees were unstable the position of the lower legs ranging between normal and anterior dislocation (Fig 2) Measurement of the tubular bones in the hands revealed a pattern profile consistent with the Larsen syndrome (Fig 3)

Laboratory findings

Examination of the blood and urine including urine chromatography revealed nothing abnormal and serologic tests for rubella and herpes virus toxoplasma listeria and cytomegalic virus were negative The caryotype was normal

Autopsy findings

The heart had a wide ventricular septal defect involving the mitral and tricuspid rings and valves The skull was normal except for the two cephalhematomas There was no sign of intracranial bleeding and the exterior of the brain appeared normal but dissection of the brain revealed three separate plaques of grayish discoloration resembling droplets of a wax candle Two of these plaques 4 and 7 mm in diameter respectively were situated in the left lateral ventricle and one sized 3 mm in the floor of the right lateral ventricle (Fig 4) All other internal organs were normal except for changes attributed to cardiac failure Dissection of the knees showed the cruciate ligaments to be elongated but no further abnormality was found in the joints

On histologic examination of the brain the plaques mentioned proved due to subependymal glial proliferation of a type described as phacomatous or hamartomatous

DISCUSSION

Conditions to be considered in the differential diagnosis of the Larsen syndrome include several malformations bone dysplasias and other inheritable diseases such as isolated congenital subluxation of the knee arthrogryposis, the Marfan and Ehler Danlos syndromes and the oto palato digital syndrome Most of these are as a rule easy to exclude According to Silverman (8) the combination of anterior dislocation of the knees and a characteristic facial appearance is sufficient evidence of the Larsen syndrome In the present case the diagnosis was further supported by the bilateral metatarsus varus deformity the malformation of the heart the pattern profile of the hands and the lack of ossification in the pubic bones

Deformities of the feet were as mentioned found in all 6 cases reported by Larsen et al (3) and have been a frequent finding also in the other cases of the syndrome Although the type of the anomaly has often not been specified both valgus and varus deformities are on record Similarly although cardiac malformation has been observed or suspected in several instances of the syndrome but not always specified this malformation has differed in nature from one case to another Ventricular septal defects have been observed in some of the previous cases

Pattern profile analysis of the tubular bones in the hand is a method of investigation elaborated by Poznanski et al (6) and found to be valuable in the discrimination between several kinds of bone dysplasias The reference curve given in Fig 3 represents the pooled measurements in several cases of the Larsen syndrome studied by Poznanski According to this author a similar pattern profile has been found only in the oto palato-digital syndrome (5)

Fig 2 1 days of age Absence of ossification in epiphyses and pubic bones Underm neralised zones in metaphyses and pelvic bones Metatarsus varus deformity Instability of knee joints (two lateral views of same knee)

The pubic bones seem to have appeared normal in most cases of the Larsen syndrome but they were unossified at birth in 2 of the 5 cases reported by Silverman (8) In one of these cases ossification of the pubic bones was found to begin between the ages of 5 1/2 months and 2 years but at 6 1/2 years it was still limited to the lateral parts of the

bones A similar delay in the ossification of these bones is a well known feature in cleido cranial dysplasia and in spondyloepiphyseal dysplasia, but then in combination with other osseous abnormalities not consistent with the Larsen syndrome

The absence of epiphyseal ossification centres in the present case might be explained by the low gestational age alone but this finding has been reported also in full term new born babies with the Larsen syndrome On the other hand the undermineralised zones seen in the metaphyses and small bones are generally considered an entirely non specific effect of disturbed metabolism In our case they may be attributed to the circulatory insufficiency after birth

Most of the findings made at autopsy also agree with previous reports The knees have been dissected in at least 3 previous cases of the Larsen syndrome (1 2, 3) In all of these the cruciate ligaments existed but appeared elongated and in one case the joint capsule was described as being abnormally wide On the other hand the lesions found in the brain were unexpected

The three plaques of glial proliferation situated subependymally in the lateral ventricles were macro and microscopically similar to the lesions seen in tuberous sclerosis but no such lesions were demonstrated elsewhere and no further characteristics of epiloia were present Neither tuberous sclerosis nor any other abnormality of the central nervous system is known to occur in the Larsen syndrome In one of the original cases described by Larsen et al (3) complete postmortem examination of the brain had been performed by a neuropathologist who discovered nothing remarkable This seems however to be the only previous case of the syndrome in which autopsy included a thorough examination of the brain It thus remains uncertain whether the glial proliferation was merely coincidental in the present case or should be considered one of the many facultative components of the Larsen syndrome

CASE REPORT

DELETION OF THE SHORT ARM OF CHROMOSOME NO 10

R BERGER J C LARROCHE and P L TOUBAS

From the Centre de Recherches de Biologie du Developpement Foetal et Neonatal and Service de Medecine Neonatale (Pr A Minkowski) Hopital Port Royal Paris France

ABSTRACT Berger R Larroche J C and Toubas P L (Centre de Recherches de Biologie due Developpement Foetal et Neonatal and Service de Medecine Neonatale Hopital Port Royal Paris France) Acta Paediatr Scand 66 659 1977 —A new case of deletion of the short arm of chromosome no 10 is reported The individualization of a new autosomal syndrome associated with a 10p- aberration is discussed

KEY WORDS Chromosomal aberrations chromosome no 10 deletion 10p

Banding techniques have made possible the description of new syndromes attributable to autosomal aberrations Among them a few cases of group C autosome deletion have been reported A new case of deletion of the short arm of chromosome no 10 is reported here

CASE REPORT

The propositus a male infant was born on April 76 1976 He was the first child of healthy unrelated parents The mother was 38 years old and the father 49 years old and both were in good health with no significant medical history The mother had a provoked abortion 14 years ago and a spontaneous miscarriage at 2 months gestation 4 years ago

The present pregnancy and delivery were normal Delivery occurred at 34–35 weeks of gestation the weight was 2700 g the length 49 cm and the head circumference 31 cm The Apgar score was 6 at 1 minute and 9 at 10 minutes Because of moderate respiratory distress the child was placed in an incubator

Numerous morphological abnormalities were noted (Fig 1) microphthalmia antimongoloid slant of the palpebral fissures hypertelorism epicanthal folds wide and flat nasal bridge everted nostrils prominent upper lip small and low set-ears with flattened helix prominent anthelix and adherent lobule micrognathia short neck widely spaced nipples dehiscent linea alba small penis left undescended testis club hands and club feet No dermatoglyphic abnormalities were seen

Fig 1 Front and side view of the propositus (post mortem)

Parental karyotypes	normal	normal	normal	normal

been identified as 10p13 following Paris Conference (1971) nomenclature (Fig 2) The karyotype of both parents were normal

DISCUSSION

Four cases of constitutional deletion of the short arm of chromosome no 10 have been published One of them (1) is a monosomy for band 10p15 and a trisomy for bands 10q20 to 10q26 resulting from a maternal pericentric inversion Therefore the present case cannot be compared to the other cases Another infant (2) had been studied before banding techniques were available and no acurate identification of the deletion was possible In the two other cases (3 4 7) the break point was at band 10p13

The comparison of the phenotypes of 4 cases of 10p- (Table 1) shows that some abnormalities were found in several cases such as antimongoloid slant of the palpebral fissures flat nasal bridge, micrognathia widely spaced nipples cardiac and urinary tract abnormalities hernia hand and foot anomalies hypoplasia or absence of the olfactory bulbs and tracts Three out of four children died prematurely

Ten cases of trisomy for the short arm of chromosome no 10 are known (5 6 and 8 for review) Some of the abnormalities of the associated phenotype may be considered as antithetical (contretype) of some of those of the deletion phenotype such as prominent nasal bridge (versus flat) and large ears (versus small)

In spite of the small number of cases it appears that a new syndrome associated with a deletion of the short arm of chromosome no 10 may be recognized

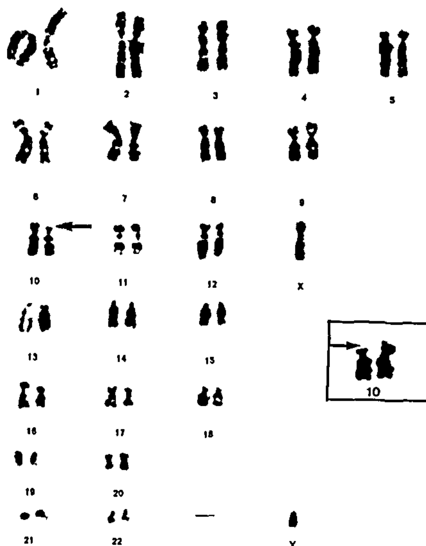

Fig 2 Karyotype (G bands) 46 XY del(10)(p13) In the frame magnification of the no 10 chromosomes

During the following hours the respiratory distress disappeared however the child remained cyanotic Complementary examination showed the existence of cardiac and urinary malformations Routine laboratory examinations were normal The child died on April 28 1976 at the age of 2 days

NECROPSY FINDINGS

The most salient features were as follows Visceral malformations dehiscent abdominal muscular wall (1 cm) truncus arteriosus hypoplasia and orificial atresia of the pulmonary artery absence of ductus arteriosus, intraventricular defect, abnormally large bronchial arteries abnormal histological aspects of the pulmonary arteries cystic dysplasia of the left kidney segmental dysplasia of the right kidney and common fibrous capsule of adrenal and kidneys Other pathological findings moderate amniotic fluid aspiration lobar hyaline membranes formation and slight degree of tubulopathy Brain abnormalities hypoplasia of the left olfactory bulb Growth morphological development was compatible with 36 weeks of gestation

LETTER TO THE EDITOR

Sir

Streptomycin and Isoniazid Metabolism in Malnourished Children

The paper by Akbani et al (*Acta Paediatr Scand* 66 237 1977) was of considerable interest as studies into drug metabolism in malnutrition are badly needed

However in the context of the abovementioned paper it should be pointed out that 2 problems arose which make data interpretation difficult Firstly the patients were only studied once namely when malnourished and not on recovery This would have allowed a comparison between admission and discharge status Secondly with regard to Streptomycin no data was provided with regard to protein binding and indeed serum albumin concentrations were not discussed

In the context of microbiological assays as were employed for the streptomycin assay it is the free (non protein bound) component of the drug which is measured Thus in hypoalbuminaemic patients assays should be performed against their own serum prior to antimicrobial therapy This does not appear to have been done in the present study and may well have affected the results This could have accounted for the relatively high peak levels seen at 30 minutes (mean 44 3 $\mu g/ml$)

To exemplify this statement studies from our laboratory using ^3H Dihydrostreptomycin sequesulphate with kwashiorkor serum (Albumin=2 4 g/100 ml) and normal serum (4 05 g/100 ml) in vitro have shown that streptomycin is 65% free in normal serum but 81% free in kwashiorkor serum (Fig 1) This could well have a significant effect on microbiological assays

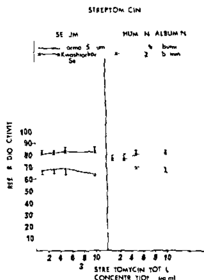

Fig 1 The binding of ^3H streptomycin to normal serum kwashiorkor serum and 4% and 2% human albumin The data represents the mean +1 S D

The present comments are not designed to detract from the value of the report in question but to draw attention to the technical problems associated with microbiological assays under such circumstances

Preparation of Manuscripts

Contributors are requested to pay particular attention to the following rules governing the preparation of manuscripts *Failure to follow these rules is a frequent cause of delay in the publication of articles and may result in rejection of otherwise acceptable manuscripts*

Manuscripts should be sent, in duplicate to the office of the Managing Editor Professor C G Bergstrand Department of Paediatrics Malmö Allmänna Sjukhus S-214 01 Malmo Sweden mailed flat and transmitted by first class mail They should be double spaced typewritten on one side of the paper with wide margins Authors should exercise particular care in the preparation notation and description of figures and tables Each table must be accompanied by a descriptive title typed above the table to which it refers A suitable legend must be provided for each figure Oversized original illustrations should be photographed and a print on glossy paper submitted A separate *title page* is necessary and should bear a) the title b) the initials and names of the authors c) the institution of origin Below the list of references the principal author should state his address to which the proofs are to be sent

A short *abstract* not exceeding 200 words must accompany each manuscript informing about problem, methods results and conclusions Unexplained abbreviations and references are not allowed The abstract must be typed on a separate sheet and styled as illustrated

ABSTRACT Köhler L and Holst K (Department of Paediatrics University Hospital Lund Sweden) Dental health of four year-old children Acta Pædiatr Scand 00

An unselected population of 1 567 four year-old children

KEY WORDS Pre school children caries gingivitis

A *summary* is usually not necessary but may be allowed if the author (or the Editor) finds it essential A summary should be typed immediately after discussion"

References to the literature should be limited to those quoted by the author The reference list should be arranged alphabetically and numbered giving name of author (authors) initials, full title of paper name of journal abbreviated in accordance with the style of *Index Medicus* (*New Series*) followed by the volume number page number and year *In this system of abbreviation periods are omitted*

1 Brecher G & Stohlman F Jr Humoral factors in erythropoietin *In* L M Tocantins & R Penn (eds) *Progress in hematology* Gruno & Stratton, New York 1959 p 110
2 Smith C A. *The physiology of the newborn infant* Thomas Springfield Ill 1967 3rd ed vol 2 p 120
3 Vedra, B & Ulrych, J. Anaerobiosis in normal and asphyxiated premature newborns 2 Four approaches *Acta Paediatr Scand* 49 129 1960

Italics are marked in the manuscript by underlining

Abbreviations must conform to accepted standards When in doubt authors are advised to consult a recent issue of the journal The SI system should be used Laboratory slang, clinical jargon and colloquialisms must be avoided

Proofs and Reprints Galley proofs will be sent to the principal author by the printer The master proof should be returned to the Managing Editor together with the manuscript within three days and by air mail if received by air mail Reprints of articles published must be ordered by separate application from *Almqvist & Wiksell S 751 81 Uppsala Sweden* to whom cheques money orders and drafts should be made payable

Manuscripts books for review and correspondence relating to the editorial management should be sent to the Managing Editor Department of Paediatrics Malmö Allmänna Sjukhus S-214 01 Malmö Sweden. Published manuscripts are not returned unless requested

	19 (Bo)	F	10 months	4	(2 300) 4 500	SFD oesophageal atresia (reop) *urinary tract infection candida* sepsis	Died

TPN given at 3 occasions for 3 14 and 11 days with 8 and 45 day intervals

verely sick infants The tolerance to amino acids is largely unknown in liver heart kidney disease respiratory insufficiency trauma infection and undernutrition—all conditions prevailing among infants requiring TPN Low birth weight infants have low activities of certain amino acid degrading enzymes (17) and intolerance to amino acids could be suspected to occur during TPN An excessive or unbalanced supply of amino acids may also lead to accumulation of metabolites due to not yet fully developed kidney function We have recently demonstrated that the cerebral uptake of certain amino acids in infants is dependent on their arterial concentrations (21) It is known that elevation and imbalance of circulating amino acids may have harmful effects (9) particularly on the developing central nervous system (26) Thus nitrogen balance and growth are not sufficiently sensitive to be the only criteria to evaluate what could be considered as an optimal supply of amino acids and other nutrients to sick infants Due to the metabolic interrelationships between the different dietary components (calorie supply will increase amino acid tolerance *amino acid supply will increase the tolerance to water potassium and fat*) and evaluation of requirements

Table 2 *Composition of TPN*

Detailed composition of the different solutions used is given in Table 4

Regimen A The daily fluid requirement was given as
1/4 = Intralipid® 20%+ Lipovit for Infants 60 ml/liter Intralipid®
1/4 = Vamin® (amino acids Na K Ca Mg Cl and fructose)
2/4 = Fructose glucose (15+5%)+heparin 0 4 ml (2 000 IU) per liter sugar solution+60 ml PED electrolyte solution per liter sugar solution Further addition of 4 N NaCl and Postoperative Potassium Solution according to requirement with daily variation according to serum analysis

Regimen B The daily fluid requirement was given as
1/4 = Intralipid® 20%+ Lipovit for Infants 60 ml/liter Intralipid®
1/4 = Amino acid solution 4200 (amino acids in water)
2/4 = Glucose 10 or 20% + heparin 0 4 ml (2 000 IU) per liter glucose+"PED electrolyte solution 60 ml/liter glucose Further addition of 4 N NaCl and Postoperative Potassium Solution according to requirement with daily variation according to serum analysis

To both regimen Water Soluble Vitamin Mixture was given separately as i v injections corresponding to 10 ml/liter glucose solution given

Supply of the different nutrients with regimen A (including 14 ml POP solution/liter carbohydrate solution) when given as 100 ml/kg and 24 hours

Energy	CHO	55 kcal (57 cal%)=13 4 g CHO (+0 43 g glycerol)

necessitates the simultaneous administration of all nutrients In order to evaluate some metabolic consequences of our regimens for TPN we have determined plasma amino acids and other circulating substrates and insulin both during the simultaneous administration of all nutrients and 30 min after discontinuation of the infusion The measurements were repeated at different occasions during the course of treatment

MATERIAL AND METHODS

Subjects

Nineteen infants were treated with TPN 11 newborns and 8 infants between 2 and 12 months of age The majority of the patients were critically ill with a variety of gastrointestinal disorders requiring surgical treatment Diagnosis age at the start of TPN duration of treatment and clinical outcome have been summarized in Table 1

Program of TPN

The program for TPN of infants were designed to cover known or recommended requirements (7 10) Two regimens were used A and B (Tables 2 and 3) which both provided similar amounts of lipid electrolytes trace elements vitamins and fluid but were slightly different with respect to the content of carbohydrate and amino acids Regimen A provided amino acids in proportions similar to those of whole egg (Vamin®) B similar to those of human milk ("4200") The relative composition of the two programs was 1/4 of fat solution 1/4 of amino acid solution and 2/4 of carbohydrate solution The detailed composition of the different solutions used including the addition of vitamins electrolytes and trace elements is given in Table 4 The amount of fluid given by continuous pump infusion

Table 1 *Clinical data of infants treated with TPN*

TPN regimen	Case no	Sex	Age	Duration (days)	Birth weight in parenthesis and weight at start of TPN (g)	Diagnosis	Outcome

TPN given at 3 occasions for 3 14 and 11 days with 8 and 45 day intervals

verely sick infants The tolerance to amino acids is largely unknown in liver heart kidney disease respiratory insufficiency trauma infection and undernutrition—all conditions prevailing among infants requiring TPN Low birth weight infants have low activities of certain amino acid degrading enzymes (17) and intolerance to amino acids could be suspected to occur during TPN An excessive or unbalanced supply of amino acids may also lead to accumulation of metabolites due to not yet fully developed kidney function We have recently demonstrated that the cerebral uptake of certain amino acids in infants is dependent on their arterial concentrations (21) It is known that elevation and imbalance of circulating amino acids may have harmful effects (9) particularly on the developing central nervous system (26) Thus nitrogen balance and growth are not sufficiently sensitive to be the only criteria to evaluate what could be considered as an optimal supply of amino acids and other nutrients to sick infants Due to the metabolic interrelationships between the different dietary components (calorie supply will increase amino acid tolerance amino acid supply will increase the tolerance to water potassium and fat) and evaluation of requirements

p indicates statistical difference between paired values obtained during TPN and 30 min after TPN (paired *t* test)
n denotes number of paired observations

ording to the analytical results If during the course of treatment plasma became opalescent the amount of lipid was reduced by 50% or completely omitted

Blood sampling and analyses

Venous blood samples were drawn (always from a different vein than that used for the infusion) during treatment with TPN and 30 min after discontinuation of the infusion In a few instances venous blood samples were also collected before the institution of TPN Venous blood was drawn into a heparinized syringe and the sample was immediately centrifuged A portion of plasma was deproteinized with christalline sulphosalicylic acid The deproteinized samples were stored in −72°C until analysis Amino acids were analysed on a Biocal 00 (Munich) automatic aminoacid analyzer according to the method of Spackman et al (23) using a lithium buffer system (3) to enable separation of glutamine asparagine threonine and serine Plasma tryptophan levels are not reliably determined by this method due to the partial binding of tryptophan to albumin The reproducibility of the amino acid analyses varies between ±3 to ±6% with the exception of cystine determination (±10) the amino acid peak of which had a tendency to overlap with the buffer change through the extreme sensitivity to buffer pH variation This amino acid also has a tendency to disappear through handling and storage of the sample Glucose (glucose oxidase Glox® AB Kabi Stockholm Sweden) free fatty acids (14) glycerol (13) D-β-hydroxybutyrate (?0) triglycerides (15) and insulin (Phadebas® Pharmacia Uppsala Sweden) were determined on plasma Lactate and pyruvate were determined on whole blood (4)

RESULTS

Clinical course

Diagnosis and clinical course are summarized in Table 1 Septic complications occurred in 8 infants in 3 instances cases 15 18 and 19 sepsis was present already before the institution of TPN Seven infants died 6 during the treatment with TPN and one a considerable time after discontinuation of TPN In none of these infants could TPN be regarded as the cause of death as judged from clinical data and autopsy findings Cases No 1 and 6 died be

concentrations moderately elevated levels of D-β hydroxybutyrate and low insulin values

Glucose and insulin values were significantly correlated ($p<0.001$) A correlation was also found between leucine and insulin ($p<0.001$) whereas no statistical relationship was found between isoleucine and insulin No statistical correlation was found between D-β hydroxybutyrate and glucose values or between alanine and D-β hydroxybutyrate values

Indices of amino acid metabolism Individual values of amino acids during TPN with regimens A and B are given in Fig 2 Mean amino acid values ±2 S D of healthy infants are included in Fig 2 Highly raised concentrations of amino acids were seen in 3 infants (cases No 1 and 6 (regimen A) and 8 (regimen B)) Mean plasma concentrations of amino acids in these 3 infants are given separately in Fig 3 There was a disproportionally large increase of plasma proline phenylalanine taurine cystine and methionine In these 3 cases concentrations of blood lactate plasma concentrations of glycerol triglycerides FFA and β hydroxybutyrate were also much above 2 S D of the normal mean values

Mean plasma values of amino acids (both regimens A and B included) determined before during and 30 min after discontinuation of TPN are given in Fig 4 Very low leucine isoleucine and valine levels and a high glycine level were present initially and did not change during treatment The mean alanine level was low at the start of the treatment became normal during treatment but returned to a low level 30 min after discontinuation of the infusion The mean urea values increased during treatment The concentrations of taurine asparagine and glutamine decreased during the infusion The mean value of methionine increased significantly ($p<0.01$) to a normal value The mean value of glutamic acid also increased significantly during treatment ($p<0.05$)

Irrespective of the regimen (A or B) used mean plasma tyrosine was low during treatment A slight metabolic acidosis not requir

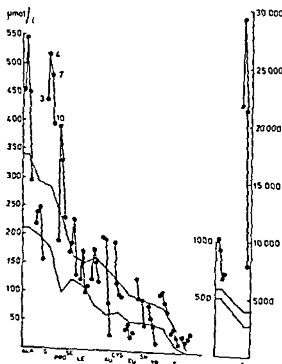

Fig 6 Plasma free amino acid levels before start of the TPN on the 3rd day of life and during the therapy on the 4th 7th and 10th day of life of case No 3 The horizontal lines represent mean ±S D of a normal material (4)

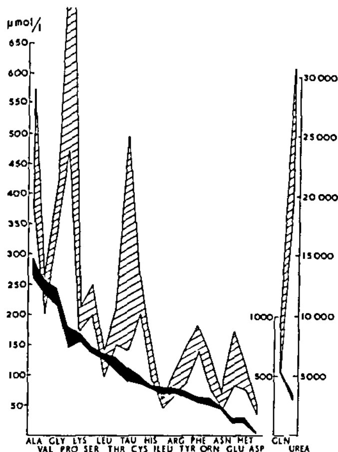

Fig 3 Plasma free amino acid levels during TPN in 3 cases (striped areas) where the therapy gave rise to a serious derangement of the stabile pattern seen under normal conditions (24) (filled area) Mean±S E M are indicated These results are included in Fig 2 and 4

cause of malformations incompatible with life case No 12 from necrotic enterocolitis complicated by sepsis case 15 from heart failure due to endocardial cushion defect and in cases 18 and 19 the primary cause of death was sepsis Thrombosis was seen in the only infant where a central vein was used for infusion (case No 18)

The clinical impression was that cases No 5 8 and 13 survived because of the treatment with TPN and that cases No 16 and 17 were greatly helped by this therapy

Metabolic findings

Indices of carbohydrate and lipid metabolism Individual values of glucose lactate pyruvate FFA glycerol D β hydroxybutyrate triglyceride and insulin during TPN with the two regimens are given in Fig 1 In several instances the values were above +2 S D of normal fasting values for infants (also given in Fig 1) Greatly elevated plasma concentrations of glucose FFA triglycerides and glycerol were often found together with elevations of one or more amino acids (in 7 out of 12 cases) Such elevations of circulating substrates were frequently associated with a poor clinical condition and seemed to be unrelated to the type of TPN regimen used Mean values of glucose lactate pyruvate FFA, glycerol D β hydroxybutyrate, triglycerides and insulin determined before during and 30 min after discontinuation of TPN are summarized in Table 5 During TPN the mean values fell within the normal range of fasting concentration with the exception of moderately elevated mean values of triglycerides and glycerol A comparison between values obtained during and 30 min after TPN using the paired *t* test showed a significant decline of glucose lactate pyruvate and triglycerides whereas D-β hydroxybutyrate values increased significantly A more pronounced drop of lactate was seen in patients receiving TPN regimen A where mean values decreased from 2 24 to 1 81 ($p<0\ 001$) Mean values 30 min after TPN was discontinued were within the normal fasting range with the exception of significantly elevated glycerol

Irrespective of the regimen (A or B) used mean plasma tyrosine was low during treatment A slight metabolic acidosis not requir

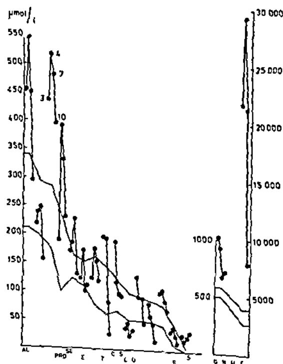

Fig 6 Plasma free amino acid levels before start of the TPN on the 3rd day of life and during the therapy on the 4th 7th and 10th day of life of case No 3 The horizontal lines represent mean ±S D of a normal material (24)

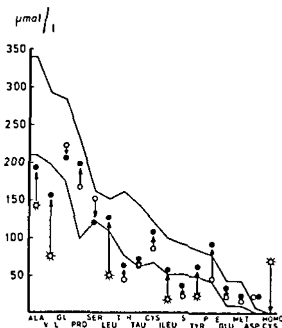

Fig 7 Plasma free amino acid levels of case 14 during TPN (open circles the low alanine branch chained and tyrosine levels characteristic of undernutrition and the homocystinaemia are indicated with stars) The filled circles represent the levels during TPN 2 days after the institution of vitamin B_6 (100 mg/day) Normal levels of infants mean ±S D (24) are indicated by the horisontal lines

ing buffer therapy was occasionally seen with both TPN regimens

Markedly elevated values of tyrosine proline serine and threonine were observed after 4 hours treatment with regimen A in case No 2 (Fig 5) Temporary elevations of some amino acids both before and after treatment for 24 hours are illustrated in Fig 6 (case No 3) As treatment continued the plasma concentrations of most amino acids decreased to the normal range and simultaneously the level of urea declined

Homocystine was detected in plasma in 2 infants One of these infants (case 14) also had low plasma concentrations of alanine valine leucine isoleucine and tyrosine during therapy with TPN (Fig 7) Following treatment with 100 mg/day of vitamin B_6 homocystine was no longer detectable in plasma and the plasma amino acid concentrations became normal within 24 hours (Fig 7)

Excessive taurinaemia of 6 500 µmole/l was seen in one icteric infant (case No 1) who was later found to have gall bladder agenesis and intrahepatic gall accumulation

DISCUSSION

The present material of very sick infants who required TPN was heterogenous with respect to age, diagnosis clinical condition, duration of treatment and number of determinations of circulating substrates and insulin TPN irrespective of the regimen used was well tolerated by the majority of infants studied However when the general condition of the infant was seriously affected with decreased peripheral circulation plasma levels of most amino acids, triglycerides glycerol FFA D-β hydroxybutyrate glucose and blood lactate were markedly elevated Therefore and because the clinical material was very heterogenous we have not performed a strict comparative evaluation of the two TPN regimens used

Before TPN was started all patients were given an electrolyte glucose solution intravenously This treatment provided only around 40 kcal/kg×24 hours^{-1} The finding of low plasma alanine concentrations elevated plasma levels of D β hydroxybutyrate FFA glycerol and glucose and low plasma insulin concentrations before TPN indicated a state of starvation During TPN the plasma concentrations of D-β hydroxybutyrate decreased by approximately 50% and the plasma alanine values became normal Already 30 min after discontinuation of TPN the plasma concentrations of D β hydroxybutyrate and alanine changed significantly D β hydroxybutyrate increased while alanine returned to a low level indicating enhanced hepatic ketogenesis and gluconeogenesis (16) None of the infants presented signs nor symptoms of hypoglycemia and the plasma insulin levels were generally low during TPN Hypoglucosemia i e a glucose value below 1 7 mmole/l was present in 3 infants (cases 1 5 19) Taken together these observations would suggest that minimal

rather than optimal amounts of carbohydrate were given

The finding of elevated blood lactate concentrations during treatment with regimen A which declined significantly 30 min after discontinuation of the infusion was most likely due to administration of fructose which was given at an approximate rate of 0 3 g/kg× hour^{-1} Our data and the fact that fructose administration could be extremely harmful in clinical situations such as hereditary fructose intolerance hepatic disease anoxic states and diabetic ketoacidosis (27) suggest that fructose should not be included in TPN The supply of lipid with regimens A and B was kept about 0 15 g/kg×hour^{-1} earlier demonstrated to be well tolerated by normal newborn infants (19) As long as the general condition of the infant was not too seriously affected this amount of lipid seemed to be well tolerated

Before TPN was started the plasma concentrations of leucine isoleucine and valine were low while the plasma glycine concentrations were high (Fig 4) This indicates protein deficiency (16) Low plasma concentrations of branch-chained amino acids have also been shown to be associated with impaired hepatic synthesis of albumin (12) However the plasma levels of leucine isoleucine valine and glycine did not become normal during TPN for an average period of 10 days suggesting either that the composition of amino acids in the infusate was inappropriate or more likely that a minimal rather than an optimal supply of essential nitrogen was given

Taurine asparagine and glutamine were not included in the infusate and the concentrations of these amino acids decreased in plasma during TPN The same was true for plasma concentration of cystine which was given in low amounts In general however the pattern of the plasma free amino acid levels did not mimic the composition of the infusate as has been suggested (24) but was rather characterized by a distortion similar to that seen in experimental and clinical undernutrition

Excessive supply of dibasic amino acids leads to metabolic acidosis (11) It is therefore possible that the slight metabolic acidosis seen in our patients was caused by a moderate overloading with dibasic amino acids A lowering of the relative amounts of these amino acids in the infusate should be considered—perhaps to a level which more closely mirrors the composition of human milk

In view of the raised demand for transport and metabolism of amino acids during TPN the need of an extra supply of vitamin B_6 as indicated by the findings in Fig 7 seems well founded A surplus of vitamin B_6 is recommended during TPN especially when given to severely undernourished infants

The present material included only one immature infant who required TPN during the neonatal period A poor tolerance to tyrosine administration—most likely due to low tyrosine amino transferase activity—is a particular problem in this situation (17) (Fig 5) The content of tyrosine was the same in both regimens and low in comparison to human milk

Elevated plasma concentrations of glycine and proline have been described in intrauterine growth retarded infants (16) Slightly elevated concentrations of plasma glycine and proline were seen in the present study both before and especially during TPN Since these amino acids can act as transmittor substances in the central nervous system (22) and theoretically could lead to neurological symptoms it is suggested that the content of glycine and proline in the infusate should be lowered

CONCLUSIONS AND RECOMMENDATIONS

Abdominal surgery in newborn babies and intractable diarrhea in infants are important indications for TPN during infancy In such situations TPN could be life saving In the case of abdominal surgery however TPN should be started early postoperatively TPN should not be given to desperate cases especially not if associated with decreased peripheral circulation Other contra indications include de

CONCLUSIONS AND RECOMMENDATIONS

Abdominal surgery in newborn babies and intractable diarrhea in infants are important indications for TPN during infancy In such situations TPN could be life saving In the case of abdominal surgery however TPN should be started early postoperatively TPN should not be given to desperate cases especially not if associated with decreased peripheral circulation Other contra indications include de

hydration severely impaired liver and kidney function and coagulopathies It is our belief that TPN should only be given on very strict indications to newborn infants particularly if prematurely born The experience with TPN in this particular group of infants is limited and must still be regarded as being at an experimental stage hitherto unknown and undesirable metabolic and neurotoxic short and long term consequences should be further explored

The results of the present study suggested that fructose should be omitted from the infusate and that vitamin B_6 should be given in excess Furthermore the present results indicated that a minimal rather than an optimal supply of energy and of amino aicds in relation to energy was provided with the two regimens used It is therefore suggested that the total volume of the infusate could be raised above 100 ml/kg×hour⁻¹ during continuous monitoring of body weight This is in agreement with the higher recommendations of Børresen (2)

The marked increase in plasma concentrations of amino acids triglycerides glucose D β hydroxybutyrate seen in some cases could indicate a lack of insulin This was especially evident in one severely SFD born infant Insulin administration and monitoring of blood glucose should be considered in such cases rather than a decreased infusion rate

The amino acid composition of the infusion can probably be considerably improved to meet with the i v requirements Regimen B has in relation to human milk a rather low content of tyrosine and phenylalanine a composition that might be favourable for immature newborn infants If treatment with regimen B continues for a longer duration the content of phenylalanine should be increased in which case the amino acid solution of regimen A could serve as an alternative

ACKNOWLEDGEMENTS

hydration severely impaired liver and kidney function and coagulopathies It is our belief that TPN should only be *given on very strict* indications to newborn infants particularly if prematurely born The experience with TPN in this particular group of infants is limited and must still be regarded as being at an experi mental stage hitherto unknown and undesirable metabolic and neurotoxic short and long term consequences should be further ex *plored*

The results of the present study suggested that fructose should be omitted from the infus ate and that vitamin B_6 should be given in ex cess Furthermore the present results indi cated that a minimal rather than an optimal supply of energy and of amino aicds in rela tion to energy was provided with the two regimens used It is therefore suggested that the total volume of the infusate could be raised above 100 ml/kg×hour^{-1} during continuous monitoring of body weight This is in agree ment with the higher recommendations of Bør resen (2)

ABNORMALITIES OF IMMUNOGLOBULINS IN INFANTS WITH CONGENITAL HEART DISEASE

A P COLE D PERRY and J R HOBBS

From the Westminster Hospital London England

ABSTRACT Cole A P Perry D and Hobbs J R (Westminster Hospital London England) Abnormalities of immunoglobulins in infants with congenital heart disease Acta Paediatr Scand 66 421 1977.—Twenty-eight infants had their serum immunoglobulins estimated (by radial immunodiffusion) in early infancy The IgG level was abnormal in twelve infants Elevated levels of IgA were found in ten and IgM in fourteen These variations mostly obvious in the first ten days of life were detected in the absence of clinical or immunological evidence of congenital rubella infection

KEY WORDS Immunoglobulins congenital malformations heart infancy

The connection between maternal rubella in the first trimester and congenital malformations has been known since 1941 (16) The diagnosis of a congenital infection with the rubella virus could be made on demonstrating a raised titre of rubella antibodies in the cord blood Epidemics of rubella may result in many affected infants with the characteristically raised IgM fraction persisting for months (8 15)

There has been speculation that other viruses could be teratogenic and the cytomegalovirus measles smallpox mumps vaccinia and varicella zoster poliomyelitis echo herpes and influenza and Coxsackie viruses have all been considered (2 10 11 12 14)

The ubiquitous nature of many maternal infections during pregnancy renders retrospective studies difficult to interpret and although twenty six viruses have proved foetopathic in animals (3 4) there is still no satisfactory animal model for the experimental production of congenital malformation of the heart

MATERIALS

Twenty-eight consecutive infants referred to three separate cardiac investigation units had their serum immunoglobulins estimated in a single laboratory Samples of blood were obtained during cardiac catheterisation or shortly afterwards In twelve cases these samples were obtained in the first two weeks of life and in none were the infants more than two months old

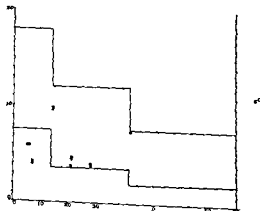

Fig 1 Serum levels of IgG against age in infants with congenital cardiac abnormalities The lines indicate the two S D limits of the log normal range for each block of age increases

ABNORMALITIES OF IMMUNOGLOBULINS IN INFANTS WITH CONGENITAL HEART DISEASE

A P COLE D PERRY and J R HOBBS

From the Westminster Hospital London England

ABSTRACT Cole A P Perry D and Hobbs J R (Westminster Hospital London England) Abnormalities of immunoglobulins in infants with congenital heart disease Acta Paediatr Scand 66 421 1977.—Twenty eight infants had their serum immunoglobulins estimated (by radial immunodiffusion) in early infancy The IgG level was abnormal in twelve infants Elevated levels of IgA were found in ten and IgM in fourteen These variations mostly obvious in the first ten days of life were detected in the absence of clinical or immunological evidence of congenital rubella infection

KEY WORDS Immunoglobulins congenital malformations heart infancy

The connection between maternal rubella in the first trimester and congenital malformations has been known since 1941 (16) The diagnosis of a congenital infection with the rubella virus could be made on demonstrating a raised titre of rubella antibodies in the cord blood Epidemics of rubella may result in many affected infants with the characteristically raised IgM fraction persisting for months (8 15)

There has been speculation that other viruses could be teratogenic and the cytomegalovirus measles smallpox mumps vaccinia and varicella zoster poliomyelitis echo herpes and influenza and Coxsackie viruses have all been considered (2 10 11 12 14)

The ubiquitous nature of many maternal infections during pregnancy renders retrospective studies difficult to interpret and although twenty six viruses have proved foetopathic in animals (3 4) there is still no satisfactory animal model for the experimental production of congenital malformation of the heart

MATERIALS

Twenty-eight consecutive infants referred to three separate cardiac investigation units had their serum immunoglobulins estimated in a single laboratory Samples of blood were obtained during cardiac catheterisation or shortly afterwards In twelve cases these samples were obtained in the first two weeks of life and in none were the infants more than two months old

Fig 1 Serum levels of IgG against age in infants with congenital cardiac abnormalities The lines indicate the two S D limits of the log normal range for each block of age increases

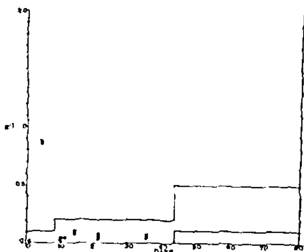

Fig 2 Serum levels of IgA against age in infants with congenital cardiac abnormalities The lines indicate the two S D limits of the log normal range for each block of age increases

The cardiac diagnoses (15 are listed in Table 1) were established by cardiac catheterisation or at necroscopy Some associated abnormalities were noted clinically or at necroscopy and in two infants multiple abnormalities conforming with the recognised Rubella syndrome occurred Virus cultures and rubella specific IgM estimations were performed and proved negative however

No infants were included in the study that had been diagnosed clinically bacteriologically or radiologically as suffering from an intercurrent infection No sera were obtained from infants after surgery

METHODS

The serum immunoglobulins were assayed by radial immunodiffusion (9) The method was calibrated using a pooled human serum which had been standardised against WHO Immunological Preparations (13) and pure human immunoglobulins The method has a between batch precision (coefficient of variation per cent) of IgG 5 2 IgA 8 4 IgM 8 5 Logarithmic normal ranges using the standard mg–International Unit contents of the WHO standards (13) and the three sections in Figs 1–3 represent ranges found for twenty five infants in the three age ranges

RESULTS

In the twenty eight sera examined the IgG level was subnormal for twelve (45%) ten of whom were under ten days old (see Fig 1) of these only two had premature birth by dates ten (40%) had raised IgA levels and of these five occurred within the first week of life (Fig 2), fourteen (50%) had raised IgM levels seven in the first two weeks of life (Fig 3) Since for the normal ranges used only 2 5% of infants should be expected either above or below the two S D limits shown, these findings are obviously highly significant Most of the diagnoses associated with raised immunoglobulin levels are shown in Table 1

DISCUSSION

The 45% incidence of subnormal IgG levels could not be explained by premature birth depriving the baby of the full maternal transfer as only two had been born prematurely nor by being small for dates due to obvious placental abnormalities It is possible that the cardiac defect itself impaired the placental circulation and thereby the transfer of IgG

The raised IgA and IgM levels especially the majority detected in the first few days after birth indicate immune stimulation within the infants (5 6)

The high incidence of raised IgA and IgM in infants with congenital heart disease provides non specific evidence in favour of intrauterine infection as a cause of abnormalities There was no maternal history pointing to any partic

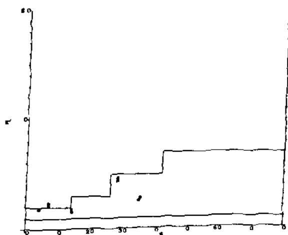

Fig 3 Serum levels of IgM against age in infants with congenital cardiac abnormalities The lines indicate the two S D limits of the log normal range for each block of age increases

ular diagnosis but symptomless rubella and other viruses i e cytomegalovirus could be considered The high incidence of respiratory infection in infants with congenital heart dis ease could explain the findings but the con siderable proportion below the age of two weeks makes this rather unlikely On the other hand the finding of raised levels in individual patients with abnormalities very unlikely to be due to congenital infection such as coarctation in Turner s syndrome suggests that some other factors apply in some individuals

Finally it seems worth noting that when gamma globulin was given prophylactically to 3 366 mothers to be in order to protect them from rubella (1) it was found that there was less heart disease and other malformations than in the control population of mothers even when all those known to be affected by rubella were excluded This could suggest that gamma globulin had protected against other unknown viruses

METHODS

The serum immunoglobulins were assayed by radial im munodiffusion (9) The method was calibrated using a pooled human serum which had been standardised against WHO Immunological Preparations (13) and pure human immunoglobulins The method has a between *batch precision (coefficient of variation per cent) of IgG* 5 2 IgA 8 4 IgM 8 5 Logarithmic normal ranges using the standard mg – International Unit contents of the WHO standards (13) and the three sections in Figs 1–3 repre sent ranges found for twenty five infants in the three age ranges

RESULTS

In the twenty eight sera examined the IgG level was subnormal for twelve (45%) ten of whom were under ten days old (see Fig 1) of these only two had premature birth by dates ten (40%) had raised IgA levels and of these five occurred within the first week of life (Fig 2) fourteen (50%) had raised IgM levels seven in the first two weeks of life (Fig 3) Since for the normal ranges used only 2 5% of infants should be expected either above or below the two S D limits shown these find ings are obviously highly significant Most of the diagnoses associated with raised immuno-globulin levels are shown in Table 1

DISCUSSION

The 45% incidence of subnormal IgG levels could not be explained by premature birth de priving the baby of the full maternal transfer as only two had been born prematurely nor by being small for dates due to obvious placental abnormalities It is possible that the cardiac defect itself impaired the placental circulation and thereby the transfer of IgG

The raised IgA and IgM levels, especially the majority detected in the first few days after birth indicate immune stimulation within the infants (5 6)

The high incidence of raised IgA and IgM in infants with congenital heart disease provides non specific evidence in favour of intrauterine infection as a cause of abnormalities There was no maternal history pointing to any partic

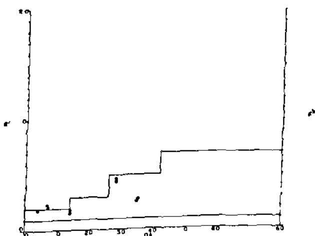

Fig 3 Serum levels of IgM against age in infants with congenital cardiac abnormalities The lines indicate the two S D limits of the log normal range for each block of age increases

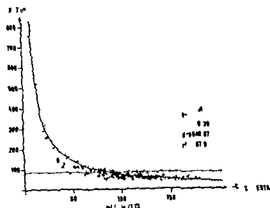

Fig 3 Plotting of plasma disappearance half time of Cr EDTA (Ti) against the clearance of [5] Cr EDTA (+=values obtained from 367 children ▲=values obtained from 28 infants) The calculated regression line is based on the values from children only The hatched area corresponds to the standard time during which measurements were obtained

Plasma creatinine was determined by the micromethod of Bartels (1) Plasma urea nitrogen was measured according to a modified urease/Berthelot method (17)

Analysis of data

In the 395 patients of the retrospective study the following relationships were examined

1 *Plasma creatinine concentration versus* Cr EDTA clearance

2 Plasma urea nitrogen concentration versus [5] Cr EDTA clearance

3 T_i versus [5] Cr EDTA clearance

4 T_i versus plasma creatinine concentration

5 T_i versus plasma urea nitrogen concentration

Regression lines were calculated for these relations according to the method of least squares using if necessary transformation of non linear curves $y=c+d/x$ to linear curves $y=c+d$ – (c_i=constant of regression line d_i–regression coefficient) Thereby it was possible to describe all examined relationships and to establish *for each* regression line the measure of determination (r^2) which describes the percentage of the total variability

The results of infants below 1 year of age were not subjected to a mathematical evaluation the *number of* patients being relatively small They were however individually plotted on the graphs

Prospective study

In the 14 renal insufficient patients in whom prospectively a prolonged measurement of the plasma disappearance half time of the test substance was performed the clearance values were obtained by two independent examiners in two different ways (*a*) using only the data of the first 85 min after the single injection of Cr EDTA (*b*) using the data found during the entire study

RESULTS

Frequency of plasma disappearance half time of ^{51}*Cr FDTA* ($T_{\frac{1}{2}}$) *being longer than 85 min*

The analysis of $T_{\frac{1}{2}}$ of 395 patients shows that in 61% of the infants and 30% of the children it was longer than 85 min Thus from the total number of observations one third of glomerular filtration rates were calculated on the basis of extrapolated data

Plasma creatinine concentration versus ^{51}*Cr EDTA clearance*

Fig 1 represents the relation between plasma creatinine concentration and the ^{51}Cr EDTA clearance An inverse relationship is observed In this graph it is quite obvious that almost all values of infants (triangles) are below the regression curve indicating that at comparable rates of glomerular filtration the plasma creatinine concentration in infants is usually lower than in children

Plasma urea nitrogen concentration versus ^{51}*Cr EDTA clearance*

Fig 2 shows the inverse relationship between plasma urea nitrogen concentration and ^{51}Cr

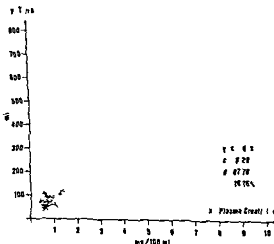

Fig 4 Plotting of plasma disappearance half time of ^{51}Cr EDTA ($T_{\frac{1}{2}}$) against plasma creatinine concentrations (+=values obtained from 157 children ▲=values obtained from 10 infants) Regression line calculated from the values of children only

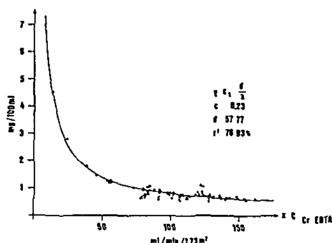

Fig 1 Plotting of plasma creatinine concentrations against $C^{51}Cr$ EDTA (+=values from 157 children ▲= values from 10 infants) The calculated regression line is based on the values from children only

late with GFR (7 9 10 11 20) it seemed likely that these parameters also correlate with the plasma disappearance half time of the reference substance Thus it might be possible to predict individually the time schedule of a single injection clearance study on the basis of plasma creatinine and/or urea concentrations

395 individual determinations of GFR by means of a single injection of ^{51}Chromium ethylenediaminotetraacetate (^{51}Cr EDTA) were analyzed mostly as a retrospective study A small number of renal insufficient patients was prospectively studied Practical conclusions may be drawn from this study improving the quality of determination of glomerular filtration rate by single injection techniques

MATERIAL AND METHODS

Patients

During three consecutive years 395 patients aged 1½ months–16 years had determinations of glomerular filtration rate by means of single injection of ^{51}Cr EDTA These patients either had mild to severe renal insufficiency or renal insufficiency was suspected or renal function needed to be documented for other reasons

Table 1 shows the 395 patients divided into different groups according to whether or not plasma values of creatinine and/or urea nitrogen were determined immediately prior to the study The results of 28 infants below 1 year of age and 367 children aged 1–16 years were retrospectively studied An additional 14 studies were performed prospectively in 14 patients with renal insufficiency in whom after the standard procedure the time of observation was prolonged up to 8 hours (Table 1)

Table 1 *Selection of patients for analysis of the correlation between plasma creatinine and/or urea nitrogen levels and T½ of ^{51}Cr EDTA*

Tabulation of 395 patients in whom glomerular filtration rate was determined The patients are grouped according to age and according to whether or not determination of plasma concentrations of creatinine and/or urea nitrogen were available at the time of the single injection clearance

Plasma concentration measured		*Number of patients*		
Creatinine	Urea nitrogen	<1 y	1–16 y	<1y –16y
+	+	7	136	143
+	–	3	11	14
–	+	5	43	48
–	–	13	177	190
Total number of patients		28	367	395

Methods

A standardized technique for determination of GFR by single injection of ^{51}Cr EDTA was used as described by Donath (4 15 16) Its comparability with the classical clearance technique was tested in our laboratory (21) All patients were studied in a recumbant position Comparable handling was warranted by the fact that they were all examined in a metabolic ward run by specially trained nursing staff For each study 8 blood samples were obtained during the 85 min after injection of the reference substance in 395 patients

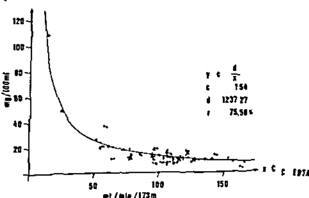

Fig 2 Plotting of plasma urea nitrogen concentrations against $C^{51}Cr$ EDTA (+=values from 191 children ▲= values from 12 infants) The calculated regression line is based on the values from children only

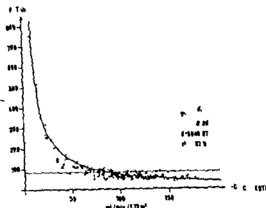

Fig 3 Plotting of plasma disappearance half time of ^{51}Cr EDTA (T½) against the clearance of ^{51}Cr EDTA (+=values obtained from 367 children ▲=values obtained from 8 infants) The calculated regression line is based on the values from children only The hatched area corresponds to the standard time during which measurements were obtained

Plasma creatinine was determined by the micromethod of Bartels (1) Plasma urea nitrogen was measured according to a modified urease/Berthelot method (17)

Analysis of data

In the 395 patients of the retrospective study the following relationships were examined

1 *Plasma creatinine concentration versus* ^{51}Cr EDTA clearance

2 Plasma urea nitrogen concentration versus ^{51}Cr EDTA clearance

3 T½ versus ^{51}Cr EDTA clearance

4 T½ versus plasma creatinine concentration

5 T½ versus plasma urea nitrogen concentration

Regression lines were calculated for these relations according to the method of least squares using if necessary transformation of non linear curves $y = c + d/x$ to linear curves $y = c + d$ — (c =constant of regression line d = regression coefficient) Thereby it was possible to describe all examined relationships and to establish for each regression line the measure of determination (r^2) which describes the percentage of the total variability

The results of infants below 1 year of age were not subjected to a mathematical evaluation the number of patients being relatively small They were however individually plotted on the graphs

Prospective study

Plasma urea nitrogen concentration versus ⁵¹Cr EDTA clearance

Fig 2 shows the inverse relationship between plasma urea nitrogen concentration and ⁵¹Cr

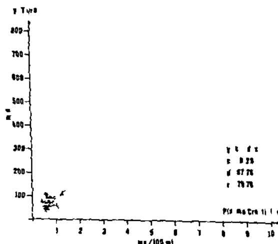

Fig 4 Plotting of plasma disappearance half time of ⁵¹Cr EDTA ($T_{½}$) against plasma creatinine concentrations (+ = values obtained from 157 children ▲ = values obtained from 10 infants) Regression line cal ulated from the values of children only

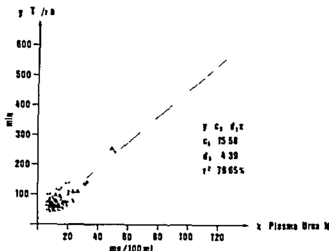

Fig 5 Plotting of plasma disappearance half time of ^{51}Cr EDTA ($T_{\frac{1}{2}}$) against plasma urea nitrogen concentration (+=values obtained from 191 children ▲=values obtained from 12 infants) *Regression line calculated from* the values of children only

EDTA clearance The values of infants (triangles) do not seem to differ from the values of children

T½ versus ^{51}Cr-EDTA clearance

Fig 3 shows the relation between the observed $T_{\frac{1}{2}}$ and the calculated ^{51}Cr EDTA clearance It can be seen that $T_{\frac{1}{2}}$ is inversely proportional to the clearance of ^{51}Cr-EDTA The values of infants represented by the triangles are clustered around this regression curve if GFR is near to normal adult values However when GFR is smaller than 60–50 ml/min per 1 73 m² the values are all situated towards the left side of the curve indicating that in the presence of the low GFR in this age group $T_{\frac{1}{2}}$ is shorter in infants than in children

T½ versus plasma creatinine and plasma urea nitrogen concentrations

The relationship between $T_{\frac{1}{2}}$ and plasma creatinine and urea nitrogen concentrations respectively are shown in Fig 4 and Fig 5 The relationship in infants between $T_{\frac{1}{2}}$ and plasma creatinine concentration (triangles Fig 4) seems to differ from the data obtained from children indicating rather longer $T_{\frac{1}{2}}$ despite low plasma creatinine concentration Such a difference between infants and children in the relationship of $T_{\frac{1}{2}}$ and plasma urea nitrogen concentration is not observed (triangles Fig 5)

Standard single injection clearance versus adapted technique in children with reduced GFR

In Fig 6 the correlation is shown between clearance values of children with reduced GFR calculated on the basis of $T_{\frac{1}{2}}$ as read from a decay curve described by data obtained during the 85 minutes following single injection (standard technique) and $T_{\frac{1}{2}}$ as read from a decay curve described by all data obtained in the same but prolonged study (adapted technique) (Fig 6) All points lie above the expected line of identity indicating persistantly higher clearance values when the standard technique was used to estimate GFR

DISCUSSION

The retrospective analysis of 395 patients in whom ^{51}Cr-EDTA single injection clearances were performed shows one of the major pitfalls of such a standardized procedure Using the standard technique the plasma disappearance curve of the injected test substance is

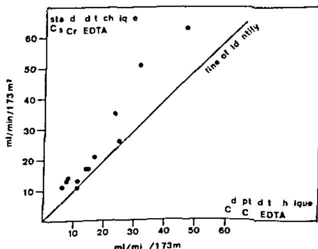

Fig 6 Correlation between clearance values calculated from the disappearance curves of ^{51}Cr EDTA as they presented on the basis of values obtained during the 85 min after injection of ^{51}Cr EDTA (standard technique) and on the basis of the entire prolonged study (adapted technique) *Each point thus represents a pair of data obtained* from one study

only measured up to 85 min This arbitrary time limit is based on the assumption that the plasma disappearance half time of the test substance is found within these 85 min However this assumption is often wrong and plasma disappearance half time exceeding 85 min have to be read by extrapolation This was necessary in 30% of children i e in the cases of moderate to severe renal insufficiency and in 61% of the infants i e in all infants including those with appropriate renal function Extrapolation automatically multiplies the minimal error of a decay curve constructed from the measured values In addition during the first 85 min of a study a pseudo-equilibration of the test substance might be observed yielding shorter than appropriate plasma disappearance half time and consecutively higher than actual GFR s This is most likely the explanation for the findings in an earlier study from this unit (21) where the single injection technique was shown to overestimate true GFR (clearance of inuline) when GFR was below 70 ml/min per 1 73 m² The 14 prospectively studied patients with GFR s below 50% of normal reported in the present paper confirm that equilibration of the test substance is incomplete after 85 min since all but one study led to higher GFR values when only the measurements during the standard 85 min were used Clearances calculated from extrapolated decay curves seem to be unreliable and it is concluded that an adaptation of the timing of ^{51}Cr EDTA clearance studies is necessary in order to obtain results more closely representing true GFR

In the present work possible indicators were examined which would allow to predict the approximate plasma disappearance half time before the clearance study An inverse proportionality between plasma creatinine and urea nitrogen concentrations respectively and glomerular filtration rate was demonstrated This relationship found in the paediatric age group is very similar to the data published by Mertz et al for adults (9 10) Similarly an inverse relationship was found between plasma disappearance half time and clearance of ^{51}Cr EDTA Therefore it was expected to find a linear relationship between $T\frac{1}{2}$ and plasma creatinine and $T\frac{1}{2}$ and plasma urea nitrogen concentration respectively This relationship was found indeed and it allows to predict with useful precision the plasma disappearance half time from plasma creatinine and/or plasma urea nitrogen concentrations It is suggested therefore to measure plasma creatinine or urea nitrogen concentration or both prior to the single injection clearance study The time schedule for an individual study can then be read from a graph as presented in Figs 4 and 5 According to the present data either indicator can be used with about the same adequacy Adapting the time schedule of the study to the predicted plasma disappearance half time makes extrapolation unnecessary or it prevents at least multiplying mistakes in constructing the plasma disappearance curve Thus it eliminates the most important pitfalls of performing single injection clearances

Infants exhibited lower plasma creatinine concentrations than children when compared with corresponding ^{51}Cr EDTA clearances The values were mostly below the regression line obtained from children reflecting the physiological finding that plasma creatinine levels are lower in infants than in older children (5 8) and the low plasma creatinine concentrations of infants are normally associated with a relatively low glomerular filtration rate (6 17 22) This is most likely due to the lower muscle mass of infants (14 23) Such a difference between children and infants was not observed for the relationship between plasma urea nitrogen concentrations and GFR Since the plasma urea level is very much dependent of the diet (18) nutritional factors might explain this observation Thus in infants plasma urea nitrogen concentrations might be used in a similar way as in children to predict the time schedule of a single injection clearance study Plasma creatinine concentrations however do not allow to predict the time schedule in infants

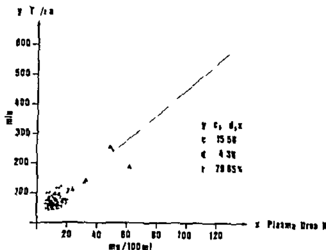

Fig 5 Plotting of plasma disappearance half time of [51]Cr EDTA (*T½*) against plasma urea nitrogen concentration (+=values obtained from 191 children ▲=values obtained from 12 infants) Regression line calculated from the values of children only

EDTA clearance The values of infants (triangles) do not seem to differ from the values of children

T½ versus [51]Cr EDTA clearance

Fig 3 shows the relation between the observed *T½* and the calculated [51]Cr-EDTA clearance It can be seen that *T½* is inversely proportional to the clearance of [51]Cr EDTA The values of infants represented by the triangles are clustered around this regression curve if GFR is near to normal adult values However when GFR is smaller than 60–50 ml/min per 1 73 m² the values are all situated towards the left side of the curve indicating that in the presence of the low GFR in this age group *T½* is shorter in infants than in children

T½ versus plasma creatinine and plasma urea nitrogen concentrations

The relationship between *T½* and plasma creatinine and urea nitrogen concentrations respectively are shown in Fig 4 and Fig 5 The relationship in infants between *T½* and plasma creatinine concentration (triangles Fig 4) seems to differ from the data obtained from children indicating rather longer *T½* despite low plasma creatinine concentration Such a difference between infants and children in the relationship of *T½* and plasma urea nitrogen concentration is not observed (triangles Fig 5)

Standard single injection clearance versus adapted technique in children with reduced GFR

In Fig 6 the correlation is shown between clearance values of children with reduced GFR calculated on the basis of *T½* as read from a decay curve described by data obtained during the 85 minutes following single injection (standard technique), and *T½* as read from a decay curve described by all data obtained in the same but prolonged study (adapted technique) (Fig 6) All points lie above the expected line of identity, indicating persistantly higher clearance values when the standard technique was used to estimate GFR

DISCUSSION

The retrospective analysis of 395 patients in whom [51]Cr EDTA single injection clearances were performed shows one of the major pitfalls of such a standardized procedure Using the standard technique the plasma disappearance curve of the injected test substance is

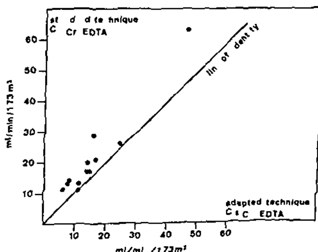

Fig 6 Correlation between clearance values calculated from the disappearance curves of [51]Cr EDTA as they presented on the basis of values obtained during the 85 min after injection of [51]Cr EDTA (standard technique) and on the basis of the entire prolonged study (adapted technique) Each point thus represents a pair of data obtained from one study

only measured up to 85 min This arbitrary time limit is based on the assumption that the plasma disappearance half time of the test substance is found within these 85 min However this assumption is often wrong and plasma disappearance half time exceeding 85 min have to be read by extrapolation This was necessary in 30% of children i e in the cases of moderate to severe renal insufficiency and in 61% of the infants i e in all infants including those with appropriate renal function Extrapolation automatically multiplies the minimal error of a decay curve constructed from the measured values In addition during the first 85 min of a study a pseudo equilibration of the test substance might be observed yielding shorter than appropriate plasma disappearance half time and consecutively higher than actual GFR s This is most likely the explanation for the findings in an earlier study from this unit (21) where the single injection technique was shown to overestimate true GFR (clearance of inuline) when GFR was below 70 ml/min per 1 73 m² The 14 prospectively studied patients with GFR s below 50% of normal reported in the present paper confirm that equilibration of the test substance is incomplete after 85 min since all but one study led to higher GFR values when only the measurements during the standard 85 min were used Clearances calculated from extrapolated decay curves seem to be unreliable and it is concluded that an adaptation of the timing of ⁵¹Cr EDTA clearance studies is necessary in order to obtain results more closely representing true GFR

In the present work possible indicators were examined which would allow to predict the approximate plasma disappearance half time before the clearance study An inverse proportionality between plasma creatinine and urea nitrogen concentrations respectively and glomerular filtration rate was demonstrated This relationship found in the paediatric age group is very similar to the data published by Mertz et al for adults (9 10) Similarly an inverse relationship was found between plasma disappearance half time and clearance of ⁵¹Cr EDTA Therefore it was expected to find a linear relationship between $T_{\frac{1}{2}}$ and plasma creatinine and $T_{\frac{1}{2}}$ and plasma urea nitrogen concentration respectively This relationship was found indeed and it allows to predict with useful precision the plasma disappearance half time from plasma creatinine and/or plasma urea nitrogen concentrations It is suggested therefore to measure plasma creatinine or urea nitrogen concentration or both prior to the single injection clearance study The time schedule for an individual study can then be read from a graph as presented in Figs 4 and 5 According to the present data either indicator can be used with about the same adequacy Adapting the time schedule of the study to the predicted plasma disappearance half time makes extrapolation unnecessary or it prevents at least multiplying mistakes in constructing the plasma disappearance curve Thus it eliminates the most important pitfalls of performing single injection clearances

Infants exhibited lower plasma creatinine concentrations than children when compared with corresponding ⁵¹Cr EDTA clearances The values were mostly below the regression line obtained from children reflecting the physiological finding that plasma creatinine levels are lower in infants than in older children (5 8) and the low plasma creatinine concentrations of infants are normally associated with a relatively low glomerular filtration rate (6 17 22) This is most likely due to the lower muscle mass of infants (14 23) Such a difference between children and infants was not observed for the relationship between plasma urea nitrogen concentrations and GFR Since the plasma urea level is very much dependent of the diet (18) nutritional factors might explain this observation Thus in infants plasma urea nitrogen concentrations might be used in a similar way as in children to predict the time schedule of a single injection clearance study Plasma creatinine concentrations however do not allow to predict the time schedule in infants

The plasma disappearance half time in infants was shown to be frequently longer than 85 min even with normal GFR s for age This observation implies that in all infants it is advisable to extend the time of study up to 120 min Predicting the time schedule by means of the demonstrated indicators and adapting the time schedule of the study to the frequently observed long plasma disappearance half time in infants improves the quality of measuring GFR by means of a single injection technique in children with any degree of renal insufficiency as well as in infants The presented adaptation of the single injection clearance study is based on physiological and pathophysiological facts which have to be accounted for

SOCIO PSYCHOLOGICAL FACTORS AND METABOLIC CONTROL IN JUVENILE DIABETES

J LUDVIGSSON

From the Department of Paediatrics Linkoping University Linkoping Sweden

ABSTRACT Ludvigsson J (Department of Paediatrics Linkoping University Linkoping Sweden) Socio psychological factors and metabolic control in juvenile diabetes Acta Paediatr Scand 66 431 1977.—The influence of exogenous and environmental factors on metabolic control was studied in 58 insulin treated juvenile diabetics 6–17 years of age Duration of diabetes varied between 3–14 years and age at onset of diabetes between 1–13 years The social situation as well as knowledge about and attitudes towards diabetes among the patients and their parents were estimated by interviews questionnaires and special tests The quality of the diet exercise and insulin treatment was assessed An index of diabetic control was calculated on the basis of the patients daily urinalysis made at home Multiple regression analysis and a special statistical instrumental variable technique were used in an effort to analyse the correlations between all variables The social situation of the diabetic children was comparable with that of other Swedish children but many parents felt the economic burden of the diabetic treatment as a problem Knowledge tests showed that 25% of the parents and 62% of the patients above 12 years had unsatisfactory knowledge about diabetes However 93% of the patients seemed to have predominantly positive attitudes towards the treatment Severe psychological problems had occurred in 7 cases Food habits were appropriate among 71% of the patients and 26% had very regular exercise customs Physical exercise seemed to be the most important of the exogenous factors for the diabetic control ($p<0.001$) Among teenagers knowledge was positively correlated to positive attitudes which in turn were positively correlated to physical exercise Instrumental variable technique gave further indications of a positive influence of knowledge on control and the correlation between diabetic control on one hand and knowledge combined with positive attitudes on the other was significantly positive The results emphasize the importance of assisting young diabetic patients and their families in their socio-psychological adaptation to the strains of diabetic therapy

KEY WORDS Juvenile diabetes metabolic control treatment social situation knowledge attitudes physical exercise C peptide insulin antibodies

Current clinical and experimental data demonstrate that optimal regulation of blood glucose should be the goal in the treatment of diabetes particularly in order to prevent or minimize the development of microvascular lesions (4 7 27) It is well appreciated however that in some patients with juvenile onset diabetes such control of hyperglycemia is very difficult to achieve Many pathophysiological and environmental mechanisms obviously contribute to the maintenance of an adequate degree of diabetic control (21 28) Among endogenous factors of importance we have in a previous study demonstrated that persisting beta cell function approximately represented by measurable amounts of serum C peptide was positively correlated to a better diabetic control while a high level of insulin antibodies was negatively correlated to good control (25) The aim of the present study was to analyse in what way exogenous and environmental factors such as the quality of treatment

The plasma dısappearance half tıme ın ın fants was shown to be frequently longer than 85 mın even wıth normal GFR s for age Thıs observatıon ımplıes that ın all ınfants ıt ıs ad vıseable to extend the tıme of study up to 120 mın Predıctıng the tıme schedule by means of the demonstrated ındıcators and adaptıng the tıme schedule of the study to the frequently observed long plasma dısappearance half tıme ın ınfants ımproves the qualıty of measurıng GFR by means of a sıngle ınjectıon technıque ın chıldren wıth any degree of renal ınsuffı cıency as well as ın ınfants The presented adaptatıon of the sıngle ınjectıon clearance study ıs based on physıologıcal and patho physıologıcal facts whıch have to be ac counted for

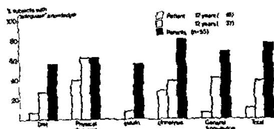

Fig 1 Knowledge about diabetes among 55 juvenile diabetics and their parents

tients >12 years old severe psychological problems diet *physical exercise* insulin dosage (IU/kg body weight) insulin frequency (1 or 2 doses a day) square root of fasting serum C peptide insulin binding capacity of IgG and index of *diabetic control during 1975*

In an effort to analyse what is cause and effect in the correlations between the variables in this cross-sectional study a special statistical technique using instrumental variables has been employed This method is discussed in detail elsewhere (22) As insulin injections and visits to the diabetic clinic were carried out by all patients irrespective of the patients attitudes these two items of the attitude tests were excluded from the statistical evaluation

RESULTS

Social situation The families belonged to social group I in 6 cases (10 3%) social group II in 18 cases (31 0%) and social group III in 34 cases (58 6%) The homes were broken in 5 cases Two patients lived in foster homes All fathers worked outside home but so did only 31 mothers (54 4%) and most of these part time only The economic situation was relatively good in most cases Still 51 families (87 9%) found the extra expenses for their child s diabetes as a moderate or great problem while 9 families (15 5%) declared that they could not afford the diabetic diet Financial support from the welfare office had been given to 11 families (19 0%) during the past 4 years

Knowledge The result of the knowledge test is shown in Fig 1 In spite of the low number of cases in some of the different subgroups the results are presented in % for the sake of comparison Thus 75% of the parents but only 38% of the teenagers reached the level considered to represent adequate knowledge There was a positive correlation between the knowledge of parents and that of their children ($r=0\ 37$ $p<0\ 01$) The parents knowledge was negatively correlated to late onset of diabetes in their children ($r=0\ 32$ $p<0\ 05$) Among patients more than 12 years knowledge was significantly correlated to positive attitudes ($r=0\ 52$ $p<0\ 005$)

Attitudes According to the interviews 52 patients (92 6%) were estimated to have predominantly positive attitudes towards the treatment of diabetes (Table 3) To the questions is there anything particular in the treatment that you dislike? 28 patients (42 0%) answered nothing , followed by the insulin injections in 12 cases (18 0%) The most readily accepted part of the treatment was physical exercise while the visits to the dia

and the patient's knowledge about and attitudes towards diabetes are related to the degree of metabolic control.

MATERIAL

A group of 58 insulin diabetics, 6–17 years of age, was studied. They were all beyond the postinitial remission period and the duration of diabetes varied from 3 to 14 years (Table 1). The age at onset of diabetes varied between 1–13 years (Table 2). Puberty according to Tanner (36) was passed in 21 (36.2%), present in 13 (22.4%) and not yet attained in 24 cases (41.4%). All patients were regularly seen at the diabetic clinic of the pediatric department 4–8 times a year. Treatment consisted of insulin, regular physical exercise, a regulated diabetic diet and daily *glucosuria control*. The latter component, however, was not introduced in the therapeutic programme until in 1970, when also more intensive efforts were made in general towards metabolic normalization. Further details regarding the material have been published elsewhere (25).

METHODS

The *social situation* of the families was analysed through personal interviews and by the means of questionnaires regarding income, education and actual job. On the basis of this information the parents were classified into social groups 1–3 in accordance with official Swedish statistics (26). Supplementary information was obtained from the tax registries and from social welfare offices.

Knowledge about diabetes and its treatment was estimated in patients and their parents (one or both) through a written knowledge test including 7 questions on diabetic diet, 2 on physical exercise, 3 on insulin, 7 on urinalysis and 7 general questions on other items such as acute complications. The questions were similar to those used by other authors (3, 6, 10, 12). Some questions which were considered to be more important than others were awarded 6 points, whereas the other questions were given 4 points. Subjects who obtained more than 3/4 of the maximum possible points were considered to have "adequate" knowledge. The test was performed under supervision without any information given beforehand and access to literature was not allowed. Three children were excluded because of low age.

Attitudes towards the treatment were studied in two ways in all but two patients who were less than 7 years old. In collaboration with the department of sociology at the University of Linköping a standardized interview was constructed containing 52 questions related to the following seven items: Content of diet, regularity of diet, physical exercise, urinalysis at home, insulin injections, visits to the diabetic clinic and regularity of the daily activities. Each answer was classified as negative, neutral or positive, giving 1–3 points respectively, and for each of the seven items the patients got a mean score from 1 (very negative) to 3 (very positive). In addition to these interviews a special attitude test was constructed in collaboration with the department of Pedagogics at the University of Linköping. It consisted of 34 provocative statements related to the same items as the interviews. Each field was covered by negative and positive statements which the patients had to accept or reject, whereby the attitudes could be classified from very negative to very positive.

Psychological assessment of the patients was made through interviews and school contacts.

The quality of the diet, exercise and insulin treatment was determined during the spring 1975. *Diet* was estimated through a 24 hour recall performed by the dietitian and the results compared with the prescribed diet (?). In this way dietary habits could be classified as "good", "acceptable" or "poor". *Physical exercise* was recorded in detail by the patients or their parents during one week. According to the kind and duration of exercise the patients were classified in three categories: Very active, ordinarily active and inactive. *Insulin dose* (IU/kg body weight) and the number of insulin injections per day were taken as a measure of the insulin treatment.

The degree of *diabetic control* was determined for the whole of 1975 on the basis of the results of the patients' daily urinalysis by the Clinitest 2 drops method made at home. From the patients' diaries the number of tests showing less than 1% glucosuria was counted and expressed in percentage of all tests performed. This figure was taken as an index of diabetic control.

Laboratory methods. C peptide and insulin antibodies were determined as described elsewhere (5, 15, 25).

Statistical methods. Multiple regression analysis was the main technique employed. The following variables were included in the evaluation: age, (age)², age at onset, (age at onset)², duration, (duration)², onset after January 1, 1970, sex, stage of puberty, social group, income, knowledge about diabetes among parents, all patients and patients >12 years old, attitudes towards the treatment of the diabetes among all patients and among pa

The *social situation* of the families was analysed through personal interviews and by the means of questionnaires regarding *income education and actual job* On the basis of this information the parents were classified into social groups 1–3 in accordance with official Swedish statistics (26) Supplementary information was obtained from the tax registries and from social welfare offices

Knowledge about diabetes and its treatment was estimated in patients and their parents (one or both) through a written knowledge test including 7 questions on diabetic diet 2 on physical exercise 3 on insulin 7 on urinalysis and 7 general questions on other items such as acute complications The questions were similar to those used by other authors (3 6 10 12) Some questions which were considered to be more important than others were awarded 6 points whereas the other questions were given 4 points Subjects who obtained more than 3/4 of the maximum possible points were considered to have adequate *knowledge* The test was performed under supervision without any information given beforehand and access to literature was not allowed Three children were excluded because of low age

Attitudes towards the treatment were studied in two ways in all but two patients who were less than 7 years old In collaboration with the department of sociology at the University of Linkoping a standardized interview was constructed containing 52 questions related to the following seven items Content of diet regularity of diet physical exercise urinalysis at home insulin injections visits to the diabetic clinic and regularity of the daily activities Each answer was classified as negative neutral or positive giving 1–3 points respectively and for each of the seven items the patients got a mean score from 1 (very negative) to 3 (very positive) In addition to these interviews a special attitude test was constructed in collaboration with the department of Pedagogics at the University of Linkoping It consisted of 34 provocative statements related to the same items as the interviews Each field was covered by negative and positive statements which the patients had to accept or reject whereby the attitudes could be classified from very negative to very positive

Psychological assessment of the patients was made through interviews and school contacts

The quality of the diet exercise and insulin treatment was determined during the spring 1975 *Diet* was estimated through a 24 hour recall performed by the dietitian and the results compared with the prescribed diet (?) In this way dietary habits could be classified as good acceptable or poor *Physical exercise* was recorded in detail by the patients or their parents during one week According to the kind and duration of exercise the patients were classified in three categories Very active ordinarily active and inactive *Insulin dose* (IU/kg body weight) and the number of insulin injections per day were taken as a measure of the insulin treatment

The degree of *diabetic control* was determined for the whole of 1975 on the basis of the results of the patients daily urinalysis by the Clinitest 2-drops method made at home From the patients diaries the number of tests showing less than 1% glucosuria was counted and expressed in percentage of all tests performed This figure was taken as an index of diabetic control

Laboratory methods C peptide and insulin antibodies were determined as described elsewhere (5 15 25)

Statistical methods Multiple regression analysis was the main technique employed The following variables were included in the evaluation age (age)^2 age at onset (age at onset)^2 duration (duration)^2 onset after January 1 1970 sex stage of puberty social group income knowledge about diabetes among parents all patients and patients >12 years old attitudes towards the treatment of the diabetes among all patients and among pa

Table 2 *Age at onset of diabetes*

	Years						Total no
	1–2	3–6	7–10	11–13	Mean	S D	
Boys	4	15	9	4	6 4	3 4	32
Girls	7	10	6	3	5 6	3 4	26

variables were kept constant The correlation between knowledge and index of control was positive though weak and there was no significant correlation between social situation and degree of diabetic control When the variables in Table 5*b* were added to those in Table 5*a* there was only a weak correlation between dietary habits and the index of control Good knowledge among teenagers about diabetes was negatively correlated to the index of control (p<0 02) while the factor positive attitudes towards diabetes was weakly correlated to control However good knowledge *combined* with positive attitudes was positively correlated to the index of control (p<0 01)

DISCUSSION

As blood glucose represents a valid indicator of the metabolism and glucosuria can be assumed to reflect the blood glucose level rather well in young people with a normal renal threshold for glucose (1 8 14 18 29 31 41) daily testing of the urine for glucose was chosen as the most accurate way to estimate metabolic control

The social situation of the diabetic children in this study was comparable with that of other Swedish children according to official statistics (32) However in all but one case the parents had to take care of their diabetic child themselves which in several cases prevented the mother to take a job outside home Many parents also felt the economic burden of the diabetic treatment as a problem (9 39) In earlier studies a relationship between social problems and poor control has been found by some investigators (33 35) but not by others (20 42) In this study there was no significant correlation between social situation and degree of control but the quality of treatment was influenced as some families had obvious difficulties in purchasing a correct diet

In spite of regular and systematic information activities many of the parents and the majority of the diabetic children even above the age of 12 years (6 10 30) had unsatisfactory knowledge about diabetes and its treatment This is in agreement with other studies (3 6 10 12 19 40 42) Previous studies have not been able to demonstrate a correlation between knowledge and degree of control (6 11 19 34 37 40) Williams et al (42) even found a negative such relationship Their results probably reflect methodological problems and do not really contradict the common opinion that a good knowledge is essential for the management of juvenile diabetes The results of the present study seem to support the hypothesis that knowledge really has a positive effect on control and this effect was especially evident when knowledge was combined with positive attitudes

Many authors have found emotional problems more often in patients with poor diabetic control than in those with good control (13 20 33 35) This was also the case in this study Although emotional stress has a diabetogenic effect on the metabolism (16 17) the occurrence of emotional problems among poorly controlled young diabetics might as

Table 4 *Diabetic control*
Index=incidence of urine tests with less than 1% glucose

Index	n	%
≥90%	3	5 3
70–89%	22	38 6
50–69%	24	42 1
<50%	8	14 0
	57	100 0

betic clinic were least appreciated Among patients more than 12 years old a late onset was correlated to negative attitudes towards the treatment ($r=0\ 35$ $p<0\ 05$) The result of the special attitude test based on provocative statements was well correlated to the result of the interviews ($r=0\ 78$ $p<0\ 001$) The special test was used as a control of the validity of the interviews and is not included in the further multiple regression analysis

Psychological situation Intellectual capacity was within normal limits in all patients Severe psychological problems leading to psychiatric consultation had occurred in 7 cases These 7 patients all but one rebellious teenagers, showed more negative attitudes than other patients towards the treatment especially towards the diet and visits to the diabetic clinic and they had a lower index of control than the rest of the patients ($p<0\ 001$)

Diet Twenty nine patients (50 0%) followed their individually prescribed dietary plans containing the daily number of exchange portions of different categories of food The comparison between the results of the 24 hour recalls and the prescribed diets showed that 12 patients (20 7%) could be considered to have good food habits 35 patients (60 3%) an acceptable and 11 patients (19 0%) a poor diet However even those with a poor diet had a roughly regulated diet without concentrated carbohydrates Patients above the age of 12 years had less good food habits than the rest ($r=-0\ 35$ $p<0\ 02$) Among these older children however there was a trend towards better food habits among those with a better knowledge about the treatment of diabetes ($r=0\ 26$ $p<0\ 10$)

Physical exercise Fifteen patients (25 9%) were classified as being very active taking part in daily sports of some kind, 15 patients (25 9%) were inactive not taking part in any sports while the remaining 28 patients (48 3%) were classified as ordinarily active Age above 12 years was negatively correlated to physical exercise ($r=-0\ 41$ $p<0\ 005$) while a positive attitude towards treatment was correlated to the degree of exercise ($r=0\ 39, p<0\ 005$)

Insulin treatment Two injections a day were given to 24 patients (41 4%) while 34 patients (58 6%) had one injection a day All patients had a morning dose of longacting insulin (Novo Lente or Monotard) in 39 cases (62 7%) supplemented by intermediate or shortacting insulin (Novo Semilente or Actrapid) The mean insulin dose per kg body weight was 1 1 IU (range 0 6–1 8)

C peptide and insulin antibodies in these patients have been presented elsewhere (25)

Diabetic control could be assessed in 57 patients (98 3%) who tested their urine regularly In the majority of cases more than 50% of the tests showed less than 1% glucosuria (Table 4)

The partial correlations between index of control and some of the clinical and laboratory variables are shown in Table 5 Thus there was a non linear relationship between index of control age and duration ($p<0\ 002$) in such a way that the index of control gradually decreased up to the age of 14 years and then increased while in relation to duration the index gradually increased up to 10 years of duration but decreased thereafter Patients with onset after 1970 had a higher index of control ($p<0\ 005$) C peptide was positively correlated to the index of control ($p<0\ 02$) while the level of insulin antibodies (IgG) was negatively correlated to control ($p<0\ 005$) Physical exercise was the only part of the treatment that was positively correlated to diabetic control ($p<0\ 001$) when all other

well be a consequence of the poor control as the cause of it

There was a rather strong evidence of a positive influence of exercise on diabetic control The lack of correlation between the adherence to a prescribed diet and the degree of control does not contradict the importance of diet Our method to estimate dietary habits are too rough especially for finding significant differences in food habits between patients like ours who all have a more or less regulated diet However the results might suggest that a strict diet does not benefit diabetic control more than a moderately regulated diet if it is properly combined with regular physical exercise adequate insulin treatment and daily urinalysis (23 38) The positive effect of adequate insulin treatment on diabetic control does not need to be proven

As diabetic control is related not only to the quality of treatment but also to endogenous factors such as C peptide and insulin antibodies (24, 25) it was advisable to include these variables in the multiple regression analysis For the same reason it was necessary to include the factor onset after Jan 1 1970 as this factor reflecting an intensification of therapy has previously been shown to be of importance for the diabetic control in the same patients as in this study (25) The findings of a positive effect of C peptide and onset after 1970 and a negative effect of insulin antibodies on diabetic control were confirmed

In conclusion the results support the view that not only endogenous but also exogenous factors influence diabetic control Of the latter physical exercise was shown to be the most important The results further indicate an association between the social situation and the treatment and support the expected importance of the patients knowledge and attitudes for the therapeutic results In addition to the classical therapeutic tools in juvenile diabetes (insulin exercise and diet) more efforts should be made to improve the patients socio psychological adaptation to the strains of diabetic therapy

ACKNOWLEDGEMENTS

My sincere gratitude to my collaborators at the departments of Mathematics Pedagogics and Sociology at the University of Linkoping I am especially indebted to Mr Erik Leander Ph D and to Mr Bengt Berglov B A for their invaluable help and advice in doing the statistics My thanks also to Mrss Ketti Andersson Eva Cornell Britt Jeirud and Helene Nordahl for their skilful assistance

This work was supported by the Swedish Medical Research Council no B 75 19X-4528 01 by the Swedish Diabetic Association and by the Medical Faculty Linkoping University Sweden

BLOOD PRESSURE IN CHILDREN AND ADOLESCENTS

CH CASSIMOS G VARLAMIS S KARAMPERIS and V KATSOUYANNOPOULOS

From the Paediatric Clinic of Thessaloniki University Thessaloniki Greece

ABSTRACT Cassimos Ch Varlamis G Karamperis S and Katsouyannopoulos V (Paediatric Clinic of Thessaloniki University Thessaloniki Greece) Blood pressure in children and adolescents Acta Paediatr Scand 66 439 1977.—Blood pressure (BP) levels were recorded in 2223 male and 2205 female children and adolescents ranging in age from 7 to 18 years In addition 521 male adults (soldiers) ranging in age from 21 to 25 years were included in the study Children and adolescents who participated in the survey were selected at random from the Elementary and High Schools The results of the study showed that a gradual increase occurred in the systolic as well as in the diastolic component of blood pressure from 7 to 18 years of age By contrast there was no increase with age in the systolic and diastolic blood pressure in the young male adult subjects who had BP measurements comparable to those observed in children A child was characterized as hypertensive according to the criteria outlined by Master et al Children with BP between the 90th and the 95th percentile were considered as suspect hypertensive whereas those with BP exceeding the 95th percentile were considered definitely hypertensive The overall incidence of hypertension in children in this survey was 3 1%

KEY WORDS Children adolescents hypertension blood pressure

There are relatively little data available in the pediatric literature regarding the level of arterial blood pressure in children (2 10 11 12) In Greece there is only one study published in a limited number of children relating blood pressure measurements to age The purpose of this study was two-fold First to obtain data regarding the distribution of blood pressure levels in different age groups in children and adolescents in Greece and compare them with those in young male adults Second to determine the incidence of hypertension in this population utilizing Master s criteria

MATERIAL AND METHODS

Children and adolescents attending the Elementary or High School as well as recruits from a large army unit (young male adult group) were included in the survey Blood pressure determinations were made in 2223 male children and adolescents 2 05 female children ranging in age from 7 to 18 years and 5?1 young male adults (soldiers) with an age of 21 to 25 years

The selection of the subjects was made as follows A certain number of elementary and high schools were picked at random from a list containing all the schools in the city of Thessaloniki Pupils attending these schools are by and large from families with an urban background Further selection of the subjects from the schools was made without any criteria from each school utilizing 1 in 3 pupils again randomly selected

In Greece elementary education for children aged 7–1? years is mandatory and approximately 95% of this population attend Elementary schools whereas 90% of adolescents attend High Schools

The selection of military recruits was made as follows One in 5 re ruits was selected at random without any predetermined criteria The origin of these recruits is representative of a cross-section population and represent urban as well as rural segments of the Greek community The socioeconomic status of the subjects was not taken into consideration

Blood pressure was recorded in the right arm by the same investigator after a 10 minute resting period A standard mercury sphygmomanometer Erkameter was utilized Depending on the arm size of the subjects two cuff sizes were used i e 9×37 and 13×39 cm² The reading on the sphygmomanometer which coincided with

Table 3 *Systolic and diastolic blood pressure measurements in young male adults according to age*

ponent There was no statistically significant difference between the sexes in different age groups with the exception of the ages of 16–18 years where the mean systolic BP was higher in the male than in the female subjects ($p<0\ 005$) It was also of interest that the 95th percentile of the systolic component of BP was higher in the male than in female subjects *in the age group of 15–18 years* ($p<0\ 005$)

A gradual increase in the mean of systolic and diastolic BP as well as 90th and 95th percentiles was noted with age

Young male adults

There was no consistent pattern in the systolic and diastolic BP measurements relating to age in the young male adults (army recruits) as shown in Table 3

Elevated blood pressure

70 male subjects out of 2223 (3 14%) had *blood pressure levels which exceeded the 95th* percentile and were considered as definitely hypertensive In the female group 69 subjects out of 2205 (3 1%) had elevated blood pressure levels i e above the 95th percentile 52 4% of the 70 male subjects had systolic hypertension only 34 2% diastolic and 14 2% systolic and diastolic elevation of blood pressure 60 9% of 69 female subjects had systolic hypertension only 32 8% diastolic hypertension only and 5 8% systolic and diastolic (Table 4) Among 521 young male subjects 44 (8 4%) had systolic and/or diastolic blood pressure levels above the 90th percentile and 17 (3 3%) *above the 95th percentile for age* (Table 5)

Table 4 *Incidence and types of hypertension in children and adolescents aged 7 to 18 years*

Number and percentage of suspect hypertensive subjects	136 (6 1%)	110 (5 0%)

'9 77 874

DISCUSSION

It is generally accepted that the determination of blood pressure in children is often neglected

the appearance of the pulse sound was recorded as the systolic component of the blood pressure whereas the reading corresponding to the complete disappearance of the sound was recorded as the diastolic component (5 8 10 11 12 18 19)

Blood pressure levels were considered elevated when they exceeded the 95th percentile In the event that the systolic and/or diastolic component were elevated blood pressure measurements were repeated a week later under similar conditions and the lowest value was considered as the final level of blood pressure The reading of the *blood pressure was done on the sphygmomanometer scale* with each division corresponding to 2 mmHg

The mean standard deviation and percentiles for each *of the three groups as well as the computation of BP* measurements in each group were calculated at the Computing Center University of Thessaloniki

RESULTS

Children and adolescents

The data of the systolic component of the blood pressure according to age and sex as well as the percentiles are shown in Table 1 Table 2 shows the results of the diastolic com

as a necessary component of the physical examination This is due to following reasons first the difficulty related to accurate recording, second the notion that idiopathic hypertension does not constitute a problem in childhood and third the lack of established normal values in different age groups for comparison (1 2 10, 11 14 21) There are few studies currently available and the data presented in these studies are not based on uniform criteria (4 10 11 15 19) More recently two surveys were published by Londe (11) and by Weiss et al (21) on 1473 and 7119 subjects respectively which were conducted in a systematic fashion

It is possible that epidemiological studies in children will shed some light on the natural history of hypertension in adults It may be that essential hypertension first appears in childhood possibly before the age of three years (19 20) Several workers have shown that a correlation exists between childhood hypertension and obesity as well as with the family history of essential hypertension in adults (11 12 23)

Deschamps et al (3) have reported an increased incidence of cerebral and cardiovascular accidents in family members of children with elevated blood pressure at the age of 4 to 6 years (3) The difference in blood pressure in the male subjects at the age of 16–18 years in our study confirms previous observations (12 13 20 21) Our data also agree with those from other surveys (11 12 19 21) regarding mean systolic blood pressure the values of 90th and 95th percentiles and the yearly increment of the systolic component of blood pressure However the mean diastolic blood pressure as well as the 90th and 95th percentiles were relatively higher in our study The average yearly increment in the diastolic blood pressure in our study was 3 mmHg which is comparable with that reported in the literature (21 22)

In the young male adult group the mean values as well as the 90th and 95th percentiles of the systolic and diastolic blood pressure neither increased with age, nor differed considerably from the corresponding values in the age group of 17–18 years It appears, therefore that blood pressure levels off between the 16th and 18th year and no further rise is observed in the male group until the age of 21 years Our findings agree with those reported in the literature (13 21)

A child was characterized as hypertensive according to Master s criteria (16) which were also utilized by Londe (11) Subjects with blood pressure between the 90th and 95th percentile were considered as suspect hypertensive while subjects with blood pressure above the 95th percentile were considered definitely hypertensive The incidence of childhood hypertension in this study was 3 1% which is in agreement with the studies of Londe (11) and Lagos et al (9)

The group of children considered as definitely hypertensive i e above the 95th percentile are currently under investigation and the findings of this study will be reported in due course

ENDOCRINE ASPECTS OF TRISOMY 4p

G GIOVANNELLI S BERNASCONI and A FORABOSCO[1]

From the Department of Paediatrics University of Parma and the [1]Institute of Human Anatomy University of Modena Italy

ABSTRACT Giovannelli G Bernasconi S and Forabosco A (Department of Paediatrics Parma and Institute of Human Anatomy Modena Italy) Endocrine aspects of trisomy 4p Acta Paediatr Scand 66 445 1977 —The main endocrinological parameters were investigated in two sisters affected with trisomy 4p Our findings rule out any impairment of the endocrine system in this rare syndrome even in those cases in which stunting of growth is more pronounced The marked weight deficit in one of the two patients had no relationship to the chromosomal anomaly it was determined by the association of a deficit of immunoglobulin with a Giardia Lamblia infestation

KEY WORDS Trisomy 4p stunted growth Giardia Lamblia infestation immunoglobulin deficiency

Trisomy of the short arm of chromosome 4 (4p+) is a newly recognized syndrome (1) characterized by mental retardation and stunted growth skeletal dysmorphism with prevalent midline distribution (2) and characteristic facial morphology

The phenotypic as well as the radiological patterns have already been described in detail (3) Stunting of growth is of variable degree out of 10 cases found in literature the height of 5 was ≤the 3rd percentile (2 9 10 11) in 3≤ the 10th percentile (12 13 14) and in 2≤the 25th percentile No endocrinological assessment of this syndrome has yet been obtained the purpose of the present paper is to fill this gap with data collected from two sisters (fig 1) in which the trisomy 4p due to maternal translocation *t* (4 22) (p11 p12) (Fig 2) has previously been documented (4)

PATIENTS AND METHODS

Case 1 M S 12 10/12 years Bone age 11 yrs by the Greulich and Pyle method Height 132 8 cm (<3rd percentile) Weight 25 2 kg (<3rd percentile)

Case 2 M N 6 4/12 years Bone age 6 years by the Greulich and Pyle method Height 111 1 cm (25th percentile)

Both cases (Fig 3) show the classical phenotype of the trisomy 4p short stature microcephaly broad thorax with widely spaced nipples prominent supraorbital margins forming a horizontal crest with the glabella hypertelorism antimongoloid slanted eyes broad bridged nose with bulbous fleshy tip mouth malocclusion low set malformed ears Radiological findings common to both patients include microcephaly small sella turcica mandibular hypoplasia with obtuse mandibular angle protrusion of the upper incisors marked hypoplasia of the first rib Y shaped configuration of clavicles right-convex scoliosis straightening of the spine in lateral projection due to absence of the physiological curvatures increase of the iliac and flattening of the acetabular angles rectangular shape of iliac crests and bilateral coxa valga

In case 2 the middle phalanges of both hands show a bowling pin appearance due to flaring of the metaphyses In case 1 small bowel examination shows the radiological pattern of a malabsorption syndrome This is related to a severe prolonged diarrhea which suddenly began at age 11 6/12 years

Intestinal biopsy (Fig 4) demonstrated a malabsorption syndrome of epithelial type with normal pancreatic secretion Schilling test=8 4% (n v ≈10–35%) Xylose test= 13 5% (n v =15%) fecal fat=5 3 g/24 h (n v =5 g/24 h) The malabsorption probably arose from a combination of a Giardia Lamblia infestation and serum immunoglobulin deficiency (IgG=355 mg/100 ml IgM=10 mg/100 ml IgA=34 mg/100 ml) Therapy directed against the Giardia

ENDOCRINE ASPECTS OF TRISOMY 4p

infestation (Furoxone® 100 mg T I D for 15 days) gave good results with the child putting on 4 kg in 3 months after almost 2 years of stationary weight

Endocrinological investigations performed are outlined in Table 1 For details see our previous publications (7 8)

RESULTS

While referring to Tables 2 and 3 for details the results can be summarized as follows

Pituitary reserve of GH Normal in both cases

Hypothalamus – pituitary – gonad axis Both FSH and LH plasma levels fall within

Fig 4 Intestinal biopsy The villi have disappeared at many points or are markedly flattened the interstitium shows oedema with much lymphatic infiltration the crypts are tortuous and elongated (H E ×30)

normal prepubertal range before and after LH RH stimulation in both cases

Hypothalamus – pituitary – adrenal axis This was investigated in case 1 only Basal secretion of 17 ketosteroids=1 24 and of 17 ketogenic steroids=5 9 mg/24 hrs with metyrapone administration the former increased to 5 4 and the latter to 43 2 mg/24 hrs Plasma cortisol levels increased regularly after ITT Altogether the functioning of the tested axis appears to be within normal limits

Hypothalamus – pituitary – thyroid axis In both cases basal values and pituitary reserve of TSH were normal as shown by the TRH stimulation test T_4 concentrations (8 5 μg/100 ml in case 1 and 7 5 μg/100 ml in case 2) T_3 test values (34 58% and 33 0%) and T_T-index values (3 11 and 2 48) were also within normal limits

Table 1 *Technical outline of the endocrinological investigations*

Hormones	Method	Material	Reference

Insulin (μU/ml)	Glucose p o	50 g/m²	29 7	–	–	53 0	–
Blood sugar (g/l)	Glucose p o	50 g/m²	0 8	–	–	1 4	–
Insulin (μU/ml)	Glucose i v	0 5 g/kg	18 0	64 0	–	29 3	–
Blood sugar (g/l)	Glucose i v	0 5 g/kg	0 9	4 1	–	2 3	–

However in case 1 the thyroid uptake of ¹³¹I was low 6% after 6 hours and 10% after 24 hours In the absence of other abnormal clinical and laboratory findings (scanning with ¹³¹I also showed a normal shaped gland with regular distribution of radioactivity) this abnormally low uptake has been considered due to a higher blood level of inorganic iodine resulting from i v pyelography performed about 1 month previously

β pancreatic function Normal in case 1 as demonstrated by plasma insulin levels after IVGTT and OGTT as well as by blood sugar levels after OGTT (6) it was not tested in case 2

CONCLUSION

No endocrine dysfunctions were demonstrated in the two patients with trisomy 4p Considering the small number of ascertained cases described up to now absence of endocrine impairment is likely to be the rule in this new syndrome Therefore even when stunting of growth is remarkable as in our case 1 an associated deficit of GH or thyroid hormones need not be considered the cause The marked weight deficit observed (in case 1) was clearly related to a malabsorption syndrome arising from the association of an immunoglobulin deficit with Giardia Lamblia infestation in fact there was rapid recovery after suitable therapy The above mentioned immunological deficit has been interpreted as an occasional transient finding not correlated with the chromosomal anomaly

ACKNOWLEDGEMENT

We are greatly indebted to Drs M Miglioli and P Vezzadini (Clinica Medica University of Bologna) for performing the intestinal biopsy and related investigations

CONTINUOUS NEGATIVE CHEST WALL PRESSURE THERAPY FOR ASSISTING VENTILATION IN OLDER CHILDREN WITH PROGRESSIVE RESPIRATORY INSUFFICIENCY[1]

SHYAMAL K SANYAL THOMAS L AVERY MOHINDER K THAPAR
WALTER T HUGHES and KENNETH S HARRIS

From the Cardiopulmonary Disease Service Intensive Care Unit and Infectious Diseases Service St Jude Children s Research Hospital Memphis Tennessee USA

ABSTRACT *Sanyal S K Avery T L* Thapar M K Hughes W T and Harris K S (Cardiopulmonary Disease Service Intensive Care Unit and Infectious Disease Service St Jude Children s Research Hospital Memphis Tennessee USA) Continuous negative chest wall pressure therapy for assisting ventilation in older children with progressive respiratory insufficiency Acta Paediatr Scand 66 451 1977.—Continuous negative chest wall pressure (CNP) was used to assist ventilation in 14 children 6 months to 14 years of age who had progressive respiratory insufficiency caused by diffuse bilateral alveolar disease Before the start of CNP therapy each child had a respiratory rate>50/min arterial oxygen tension (PaO_2)<70 mmHg ($FIO_2 \geq 50\%$) and arterial carbon dioxide tension ($PaCO_2$)<45 mmHg The mean intrapulmonary right to-left shunt was 28 7±3 8% Within 6 hours after therapy was started PaO_2 increased from 55 4±15 9 to 81 6±17 7 mmHg ($p<0\ 005$) This improvement was sustained and within 24 hours permitted a decrease in fractional concentration of inspired oxygen (FIO_2) from 51 8±6 2 to 41 0±8 4% ($p<0\ 001$) and in respiratory rate from 78 1±23 0 to 56 4±21.3 ($p<0\ 01$) There was a concomitant decrease in intrapulmonary right to-left shunt Four of the 14 patients developed pneumothorax that was successfully decompressed Ten patients survived

These observations establish CNP therapy as an effective means of improving arterial oxygenation in spontaneously breathing older children Of added significance this mode of therapy eliminates the need for endotracheal intubation and prolonged use of muscle relaxants and sedatives It also minimizes exposure to high FIO_2 thereby minimizing the hazards of pulmonary oxygen toxicity

KEY WORDS Older children continuous negative pressure respiratory insufficiency arterial oxygenation

The effectiveness of continuous negative chest wall pressure (CNP) as a means of improving arterial oxygenation is now well established in newborn infants with severe respiratory distress syndrome (2 6 14) In a recent preliminary communication (17) we suggested that CNP therapy may prove to be equally effective in management of progressive hypoxemia due to extensive lung disease in spontaneously breathing older children The purpose of this communication is to present data that establish the role of CNP therapy as a means for assisting ventilation in spontaneously breathing older children who develop progressively severe hypoxemia of pulmonary

CONTINUOUS NEGATIVE CHEST WALL PRESSURE THERAPY FOR ASSISTING VENTILATION IN OLDER CHILDREN WITH PROGRESSIVE RESPIRATORY INSUFFICIENCY[1]

SHYAMAL K SANYAL THOMAS L AVERY MOHINDER K THAPAR
WALTER T HUGHES and KENNETH S HARRIS

From the Cardiopulmonary Disease Service Intensive Care Unit and Infectious Diseases Service St Jude Children s Research Hospital Memphis Tennessee USA

ABSTRACT Sanyal S K Avery T L Thapar M K Hughes W T and Harris K S (Cardiopulmonary Disease Service Intensive Care Unit and Infectious Disease Service St Jude Children s Research Hospital Memphis Tennessee USA) Continuous negative chest wall pressure therapy for assisting ventilation in older children with progressive respiratory insufficiency Acta Paediatr Scand 66 451 1977 —Continuous negative chest wall pressure (CNP) was used to assist ventilation in 14 children 6 months to 14 years of age who had progressive respiratory insufficiency caused by diffuse bilateral alveolar disease Before the start of CNP therapy each child had a respiratory rate>50/min arterial oxygen tension (PaO_2)<70 mmHg ($FIO_2 \geq 50\%$) and arterial carbon dioxide tension ($PaCO_2$)<45 mmHg The mean intrapulmonary right to-left shunt was 28 7±3 8% Within 6 hours after therapy was started PaO increased from 55 4±15 9 to 81 6±17 7 mmHg ($p<0$ 005) This improvement was sustained and within 24 hours permitted a decrease in fractional concentration of inspired oxygen (FIO_2) from 51 8±6 2 to 41 0±8 4% ($p<0$ 001) and in respiratory rate from 78 1±23 0 to 56 4±21 3 ($p<0$ 01) There was a concomitant decrease in intrapulmonary right to-left shunt Four of the 14 patients developed pneumothorax that was successfully decompressed Ten patients survived

These observations establish CNP therapy as an effective means of improving arterial oxygenation in spontaneously breathing older children Of added significance this mode of therapy eliminates the need for endotracheal intubation and prolonged use of muscle relaxants and sedatives It also minimizes exposure to high FIO_2 thereby minimizing the hazards of pulmonary oxygen toxicity

KEY WORDS Older children continuous negative pressure respiratory insufficiency arterial oxygenation

The effectiveness of continuous negative chest wall pressure (CNP) as a means of improving arterial oxygenation is now well established in newborn infants with severe respiratory distress syndrome (2 6 14) In a recent preliminary communication (17) we suggested that CNP therapy may prove to be equally effective in management of progressive hypoxemia due to extensive lung disease in spontaneously breathing older children The purpose of this communication is to present data that establish the role of CNP therapy as a means for assisting ventilation in spontaneously breathing older children who develop progressively severe hypoxemia of pulmonary

origin and to discuss briefly the basic mechanism that might explain the improvement of arterial oxygenation produced by this mode of therapy

MATERIALS AND METHODS

Patients

The study included 14 of 34 immunosuppressed children who while receiving chemotherapy for childhood malignancies were admitted to St Jude Children s Research Hospital with progressive bilateral alveolar disease due to *Pneumocystis carinii* infection Their ages ranged from 6 months to 14 years with median of 7 years Each patient had a history of fever cough and respiratory distress of 6 to 16 days duration

Physical examinations on admission showed mild to severe respiratory distress in all patients with respiratory rates ranging from 28 to 92 per min Heart rates varied from 110 to 170 per min The lungs of each child were clear to auscultation and percussion Eleven patients were febrile and one had cyanosis

Initial laboratory data included hemoglobin values ranging from 82 to 100 g/l and total white blood cell counts from (6 8–8 2×10⁹/l) *with a predominance of neutrophils* Urine and blood cultures were sterile and throat cultures were free of pathogenic organisms Skin tests for histoplasmosis and tuberculosis were nonreactive Complement fixation titers for influenza viruses A B and C parainfluenza viruses toxoplasma and mycoplasma were all less than 1 8 Chest roentgenograms showed bilateral pulmonary densities compatible with diffuse alveolar disease

Initial acid base and blood gas profiles (Table 1)

An analysis of arterial blood samples (18 19) obtained from 13 patients *while they were breathing room air indicated* moderate to severe hypoxemia (mean arterial oxygen tension (PaO_2) 49 8±17 1 mmHg range 27 to 80 mmHg) *Acid base measurements were normal in 3 patients* while the remaining 10 had respiratory alkalosis characterized by pH≥7 5 and arterial carbon dioxide tension ($PaCO_2$)≤30 mmHg

Arterial blood gas measurements were repeated in 14 patients after they had breathed 100% oxygen for 20 min *from a nonbreathing system equipped with a Hans* Rudolph valve and an in line reservoir Before each blood gas determination the oxygen electrodes were calibrated *with gas of known oxygen tension Alveolar arterial gradients* and intrapulmonary right to-left shunts were calculated from standard formulas (3 15 19) The results *indicated abnormal intrapulmonary right to-left shunts in* all but one patient (range of values 7 to 33%)

Hospital course

After the initial acid base and blood gas studies we obtained lung aspirates from each patient by a percutaneous transthoracic approach (11 12) These contained *P carinii* organisms as demonstrated with toluidine blue O and methenamine silver nitrate stains Cultures of the aspirates were free of bacteria and fungi Either pentamidine isethionate[1] or trimethoprim sulfamethoxazole (11) as well as chlorpheniramine intravenous fluids and oxygen were administered to all patients During the next 48 to 96 hours each patient developed progressive respiratory distress and hypoxemia that necessitated an increase in fractional inspired oxygen concentration (FIO_2) from room air to 51 5±7 2% There was a concomitant increase in intrapulmonary right to-left shunt from 20 8±8 6% on admission to 28 7±3 8% Because of progressive respiratory *insufficiency and the inability to maintain PaO_2≥70* mmHg in spite of an increase in FIO_2 to ≥50% CNP therapy was started for each patient The specific criteria *for starting therapy are shown in* Table 2

CNP therapy

A modified Emerson tank respirator (17) was used to apply continuous negative pressure around the chest wall and lower part of the body Blood gases were measured serially while the pressure inside the respirator was adjusted from −1 to −18 cm H_2O The negative pressure that resulted in a PaO_2>70 mmHg was maintained When two consecutive PaO_2 values of 70 mmHg or greater were obtained 1 hour apart *FIO_2 was reduced by decrements of* 5% until 40 to 35% was reached At this point CNP was reduced by decrements of 1 to 2 cm H_2O on the basis of

serial blood-gas measurements that were repeated within 1 hour after each change in either FIO or negative pressure When PaO_2 remained at or above 70 mmHg (with FIO of ≤40%) for 2 hours without CNP the patient was removed from the tank respirator and FIO_2 was gradually reduced as tolerated to that of room air

RESUL1S

For these 14 patients the duration of CNP therapy ranged from 1 5 to 15 days (mean 6 68±5 26) Therapy was started at a negative pressure of 5 cm H_2O for 11 patients 8 cm H_2O for two and 12 cm H_2O for one child who was considered to have severe ventilatory insufficiency characterized by cyanosis marked respiratory distress PaO_2 of 27 mmHg and $PaCO_2$ of 28 mmHg In an effort to distinguish the beneficial effects of CNP therapy from those possibly produced by improvements in the lung disease itself we analyzed in greater detail those changes occurring during the first 24 hours of therapy

Amount of continuous negative pressure

During the first 12 hours of therapy the amount of CNP increased as a curvilinear

Table 2 *Criteria for starting CNP therapy*

Age (y)	Respiratory rate (per min)	PaO_2 (mmHg)	Intrapulmonary right to-left shunt (%)
1– 5	>80	<60	>24
5–10	>65		
>10	>50		

Despite increases in FIO_2 to ≥50%

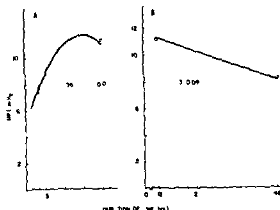

Fig 1 Kinetics of CNP during first 48 hours of therapy During the first 12 hours the amount of negative pressure was increased as a curvilinear function of time Note that the maximum increase in CNP occurred between 11 and 12 hours of therapy The amount of CNP was then decreased by 48 hours as a linear function of time

function of time reaching its maximum value between 11 and 12 hours (Fig 1) Increases in pressure during this period were positively correlated with cha iges in PaO_2 ($p<0\ 025$) and negatively with decreases in FIO_2 and respiratory frequency ($p<0\ 005$) After 12 hours CNP decreased linearly with time

Arterial oxygen tension

Within 1 hour after the start of CNP therapy absolute PaO_2 values increased in all patients but one (Fig 2) Similarly the mean PaO_2 increased from 55 4±15 9 before therapy to 74 4±35 2 within 1 hour By the end of 6 hours the increase in mean PaO was significantly different from the pre CNP mean ($p<0\ 005$) This improvement in arterial ox)genation although not linearly related to the amount of negative pressure persisted despite a continuous decrease in FIO_2 (Table 1)

Fractional concentration of inspired oxygen

During the first 2 hours of CNP therapy while negative pressure increased from a mean of 5 93±2 1 to 7 3±3 3 cm H_2O there was little change in mean FIO_2 From the 3rd to the 12th hour however the decrease in FIO_2 showed a significant negative correlation with the in

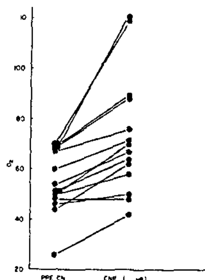

Fig 2 Effect of 1 hour of CNP therapy on arterial oxygenation in 14 patients In each patient the fractional concentration of inspired oxygen (FIO_2) and the amount of negative pressure were maintained at a constant level from the pre *CNP* period to *1* hour after therapy was begun

crease in amount of negative pressure that was applied around the chest wall ($p<0\ 005$) During this 9 hour period in which negative pressure increased from 9 6±3 0 to its maximum mean value of 11 2±2 7 cm H_2O it was possible to reduce FIO_2 by 3 46% for each increase in CNP of 1 cm H_2O By the end of 12 hours the mean FIO_2 values had decreased from a pre CNP high of 51 8±6 2% to 45 5±6 9% ($p<0\ 01$) and further to 41 0±8 4 by the end of 24 hours of CNP therapy

Respiratory frequency

Within 1 hour after CNP therapy was initiated respiratory rates started to decrease Although this trend toward improvement persisted through 48 hours respiratory rates did not become significantly different from the pre CNP mean value until the end of 24 hours ($p<0\ 01$) During the first 12 hours of therapy decreases in respiratory frequency were negatively correlated with increases in CNP ($p<0\ 005$)

Intrapulmonary right to left shunt

From a pre CNP mean of 28 7±3 8% intrapulmonary shunt decreased to 24 4±2 2% by the end of 24 hours of CNP therapy ($p<0\ 01$)

Mean values for blood pressure heart rate pH or $PaCO_2$ did not change significantly during the first 24–48 hours of CNP therapy However after initial improvement each of the four patients who died developed progressive hypoxemia, carbon dioxide retention increases in intrapulmonary right to-left shunt metabolic and respiratory acidosis tachycardia and hypotension a few hours before death

Complications

Four patients developed pneumothorax that was successfully decompressed in each case This complication occurred after 18 hours of therapy and only in those patients who had received more than 12 cm H O of negative pressure In two instances the pneumothorax involved a lung that had been the site for aspiration by a percutaneous transthoracic technique Moderate neck abrasions were noted in six patients Excessive cooling of the body did not occur None of the children showed undue apprehension while they were in the respirator nor did any survivors have adverse psychological reactions

Outcome of disease

Ten patients survived Autopsy results available for three of the four fatal cases included *diffuse and confluent alveopathy of varying severity* This process consisted of a reduction in alveolar space due to proliferation of hyper

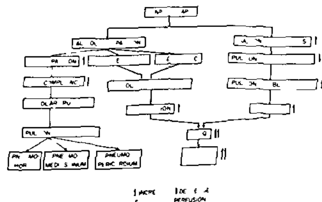

Fig 3 Proposed mechanism for effects of CNP therapy Solid lines (—) indicate the possible mechanisms for beneficial effects of CNP therapy whereas the broken lines ( ) indicate the adverse complications of pulmonary air leak VA/Q denotes ventilation perfusion ratio

plastic epithelial cells lining the alveoli and to proteinaceous eosinophilic exudate containing macrophages Widening of the intra alveolar septae due to fibrosis mononuclear cell infil trates and proliferation of congested capil laries were noted Lung specimens from two patients contained *Pneumocystis carinii* cysts

DISCUSSION

Progressively severe hypoxemia that is usually refractory to conventional modes of oxygen therapy is a common cause of death in im munosuppressed patients with diffuse bilateral alveolar disease (8 10) Management of such patients has previously required prolonged ex posure to hight ambient oxygen concentra tions with the attendant risk of irreversible pulmonary oxygen toxicity Results of the present study confirm our preliminary impres sions (17) that CNP therapy substantially im proves arterial oxygenation in spontaneously breathing older children who had severe hy poxemia of pulmonary origin Of added signi ficance such therapy eliminates endotracheal intubation and the use of muscle relaxants and sedatives and permits an early reduction in oxygen concentrations thus minimizing the hazards of oxygen toxicity

The high survival rate in this study 10 of 14 patients is in sharp contrast to our earlier ex perience with five other immunosuppressed children who presented with clinical and roentgenologic evidence of diffuse alveolar disease After detection of *P carinii* orga nisms in lung aspirates each patient was given pentamidine intravenous fluids and controlled oxygen therapy that was monitored on the basis of sequential blood gas analysis All five patients developed progressive respiratory in sufficiency and required an increase in FIO_2 Subsequently because of an inability to main tain $PaO_2 \geq 70$ mmHg despite an increase in FIO_2 to 60% or above ventilatory support with a pre set volume ventilator and PEEP was initiated The disease ended fatally in each child Similar experiences have been re ported by other investigators who appear to have met with little success using pre set vol ume respirators or membrane oxygenators in the management of progressive respiratory sufficiency due to *Pneumocystis carinii* pneu monitis (4 8 9 21)

The exact manner in which CNP therapy improves arterial oxygenation is not clear In some patients with lung disease closing capaci ty (CC) may exceed functional residual capac ity (FRC) during tidal breathing and thus pro- duce arterial hypoxemia That application of CNP around the chest wall can increase FRC has been demonstrated by Bancalari et al (2) Further Abboud et al and others (1) have shown that application of continuous distend ing airway pressure decreases closing volume Thus an increase of FRC in the face of a de crease in closing volume may reduce areas with airway closure and improve arterial oxy genation In Bancalari s study however the reported increases in FRC were not linearly related to improvements in arterial oxygena tion which suggests that the beneficial effects of CNP could be related to factors other than an improvement in the relationship between FRC and closing volume

These possible contributing factors include an increase in vascular transmural pressure (5) with a consequent decrease in pulmonary vascular resistance (16) as well as an increase in pulmonary blood flow (13) Increased pul monary blood flow in the presence of an in crease in thoracic gas volume would be ex pected to improve ventilation perfusion ratios and hence would explain the improvement in arterial oxygenation that was seen in most of our patients following the initiation of CNP therapy On the other hand a progressive in crease in negative pressure beyond a certain level can produce alveolar overdistention with a decrease in lung compliance (2) and subse quent rupture of the distended alveoli with development of pulmonary air leak as oc curred in four of our patients

Apparently then the effects of CNP ther apy depend upon whether the primary re

sponse involves recruitment of nonventilated alveoli or progressive overdistention of these structures (Fig 3) The former response would improve arterial oxygenation and thus benefit the patient whereas the latter after a certain degree of distention would compromise lung compliance and might even produce the complication of pulmonary air leak Recently Suter et al (20) reported an optimum pressure for producing beneficial effects in adults receiving positive end expiratory pressure (PEEP) for acute respiratory failure Whether there is a similar optimum level of CNP therapy for children needs further careful evaluation of cardiopulmonary hemodynamics and pulmonary function status before during and after this mode of therapy

ACKNOWLEDGEMENTS

We thank the members of the Intensive Care Unit Nursing Team and the Pediatric House Staff for care of these patients William C Maurencheck M D and Alvin M Mauer M D for their critical review of the manuscript and Mr John Gilbert for his help in preparing the manuscript

CROSS SECTIONAL STUDIES OF PHYSICAL GROWTH IN TWINS POSTMATURE AND SMALL FOR DATES CHILDREN

R N CHAMBERLAIN and R N SIMPSON

From the British Births Child Study Paediatric Unit St Mary s Hospital Medical School London England

ABSTRACT Chamberlain R N and Simpson R N (British Births Child Study Paediatric Unit St Mary s Hospital Medical School London England) Cross-sectional studies of physical growth in twins postmature and small for-dates children Acta Paediatr Scand 66 457 1977.—From 16 955 live births which occurred throughout the United Kingdom in April 1970 three groups of children who might have suffered from fetal malnutrition i e the multiple postmature and small for-dates births were selected with a 10% random sample Their birthweights and weights heights and head circumference measurements were compared at the ages of 22 months and 3½ years Differences between the random and postmature groups still present at 22 months disappeared at 3½ years Variations in the other groups persisted and the compensation occurring at 22 months had apparently ceased at 3½ years The three examinations were linked and the children including those in the control group showed considerable mobility in their quartile ratings Only a minority remained unchanged At the same time the weights of the heavier and lighter children tended to go towards the mean As the velocity of growth slowed the redistribution tended to lessen but was still taking place at the age of 3½ years

KEY WORDS Twins postmature small for-dates fetal malnutrition physical growth

To determine whether fetal malnutrition might have a permanent effect on the subsequent physical and mental development of children three groups were selected for study In the first the twins it was assumed that growth retardation might have occurred from competition between the fetuses for the available nourishment In the second the postmature babies it was thought that cessation of placental growth about the 39th week of pregnancy (7) could have resulted in malnutrition in the month or so prior to birth The third consisted of the small for dates babies who were selected because their birthweights showed evidence of growth retardation at every gestational age None of these three groups is homogeneous but each is likely to contain substantial numbers of children who could have suffered from fetal malnutrition

PLAN OF INVESTIGATION

The children were selected from the national cohort of 16955 live births in the British Births Survey which included over 95% of the births which took place during the week beginning 5 April 1970 throughout the United Kingdom (1) From the information collected at birth the sample was drawn as follows

(i) A 10% random sample of all singleton and multiple births

(ii) All multiple births i e twins and triplets

(iii) All singleton children who were born at or later than 42 weeks gestation whose mothers were recorded as being *certain of the date of their last menstrual period* and not to have taken the contraceptive pill for at least 15 months before childbirth

(iv) All singleton children who were on or below the 5th centile of *birthweight for their gestational age allowing for* sex and maternal parity but regardless of whether their mother was certain of her last normal menstrual period or had taken the contraceptive pill These children were identified using *Tanner & Thomson s charts for birth* weight and length of gestation (8)

The children of mothers who stated that they were unmarried divorced separated or widowed at childbirth

were then excluded because of the difficulties involved in tracing them The random sample was compared with its British Births Survey equivalent and no statistical difference was found below the 5% level in any of the observed characteristics

The method of sampling tracing the children and the results of the second examination have already been published (2 3) so that only an outline is given here

The groups were not mutually exclusive and related to 3471 children of whom 96 had died all between birth and the second examination 2555 or 73 6% were seen between the ages of 92 and 123 weeks or were known to have died about half being in the age range of 94 to 97 weeks At the third examination 2426 or 69 9% were seen between the ages of 3 years 16 weeks and 4 years 8 weeks or were known to have died two-thirds being seen during the twelve weeks between 3 years 18 weeks and 3 years 29 weeks Some children untraced at the second examination were found at the next and vice versa Thus 2055 or 60 9% of the living children were examined at birth and on the two subsequent occasions

Chi squared and two sample t tests were used to test for sampling errors No significant difference was found between those examined between 3 years 18–29 weeks and those examined earlier later or not examined for sex maternal height and age in any of the groups However of those examined during the twelve week period the average birthweight was slightly heavier in the postmature group and the mean gestational age was marginally longer in the small for-dates group Although there was no difference in the distribution of Social Class I–V among those examined in the twelve week period there was a slightly smaller proportion of children with fathers from the Armed Forces in the postmature and random groups there was a slightly smaller proportion of children whose mothers were having their second or third baby in the small for-dates group there was a slightly higher proportion of mothers who came from Northern Ireland among the random and a slightly smaller proportion from the West Indies among the random and twin groups None of these differences was great and only affected proportions of numerically small groups so that they are unlikely to affect the results given here

Minor differences between the proportions of children examined in each of the three four week periods between the ages of 3 years 18–29 weeks were also found for the above variables but again are unlikely to affect the results given here

The analysis

The data has been analysed as three cross sectional studies and as a longitudinal study

(*a*) *Cross sectional studies* Two sample t tests were applied to compare the differences in the physical measurements of the three groups from the random sample for boys for girls and for both sexes together The analysis included only children where measurements had not presented difficulties e g *refusal to stand still* Differences found between the results at the second and third examinations were checked by using only those children examined both times The relation between height and weight was studied using an analysis of covariance

(*b*) *Longitudinal study* The patterns of growth were analysed by dividing the heights and the weights of the children at each examination into quartiles and comparing the differences For birthweight quartiles the standards published by Thomson et al (10) which take into account sex and gestational age up to 42 weeks for singleton children were used For the height and weight quartiles the standards published by Tanner et al (9) which take into account age and sex were used but as figures were given for length only under the age of 2 years heights were extrapolated using the data for 2 years of age where both length and height were given

The data in the longitudinal study refers to a slightly different group of children than that in the cross sectional studies for as the quartiles were standardized for age it was possible to include a wider sample although restricted to those examined on all three occasions

The control group now refers to singleton children with gestational ages of 38–41 weeks (inclusive) who were examined between the ages of 92–109 weeks in the second examination and 3 years 18–29 weeks in the third and where no difficulties were recorded in taking the measurements There was no statistical variation below the 5% level between the quartile distributions of birthweight weight and height for this control group and the standards

To make them compatible the standards for birth weights of singleton children were used for the twins with gestational ages of 38–41 weeks (inclusive)

For postmature children those with gestational ages of 42 and 43 weeks were included but the standards for birthweights of 42 weeks only were used as others were not available

For the small for-dates children those with gestational ages of 38–41 weeks were included The analysis was carried out on both sexes with similar findings but to avoid repetition the results of the longitudinal study are only given for boys

RESULTS

Random sample

Table 1 gives the mean physical measurements of the boys and the girls between the ages of 3 years 18–29 weeks in the third cross sectional study At 94–97 weeks in the second study (2) the boys were significantly heavier than the girls ($p<0.001$) and this variation has remained They were still taller but the degree of difference was not so great ($p<0.001$ in the second and $p<0.01$ in the third) The velocity of growth in height of girls is quicker than that of boys until about the age of 4 years when it is the same for both sexes (9) and this probably accounts for the differences found between the two cross sectional studies

Table 1 *Mean physical measurements of boys and girls aged 3 years 18 weeks to 3 years 29 weeks excluding those with difficulties in measurements*

Table 2 shows the number and proportion of boys in each of the quartiles at the three examinations and Fig 1a shows the proportion whose weights at 92–109 weeks were in the same quartiles as their birthweights Those whose birthweights lay in Quartile I i e on or *below the 25th centile* could only remain unchanged or move to a higher quartile those in Quartile IV could only remain unchanged or move to a lower quartile while those in the middle quartiles were able to remain unchanged or move either up or down If such changes had been uniform throughout the sample and unaffected by birthweight then it would be expected that the proportion remaining unchanged in each of the inner quartiles would be about one third compared with two thirds in each of the outer groups In fact 30% and 29% were unchanged in the two inner quartiles and 35% in the first and 39% in the fourth Thus although a larger proportion of the children in *the outer quartiles remained* unchanged there was actually a greater mobility than expected amongst these children

Table 2 *Number and proportion in each weight quartile at the three examinations (boys only)*

Singleton boys with gestational ages of 38–41 weeks (inclusive)
Boy twins with gestational ages of 38–41 weeks (inclusive)
Singleton boys with gestational ages of 42 and 43 weeks

were then excluded because of the difficulties involved in tracing them The random sample was compared with its British Births Survey equivalent and no statistical difference was found below the 5% level in any of the observed characteristics

The method of sampling tracing the children and the results of the second examination have already been published (2 3) so that only an outline is given here

The groups were not mutually exclusive and related to 3471 children of whom 96 had died all between birth and the second examination 2555 or 73 6% were seen between the ages of 92 and 123 weeks or were known to have died about half being in the age range of 94 to 97 weeks At the third examination 2426 or 69 9% were seen between the ages of 3 years 16 weeks and 4 years 8 weeks or were known to have died two-thirds being seen during the twelve weeks between 3 years 18 weeks and 3 years 29 weeks Some children untraced at the second examination were found at the next and vice versa Thus 2055 or 60 9% of the living children were examined at birth and on the two subsequent occasions

Chi squared and two sample *t* tests were used to test for sampling errors No significant difference was found between those examined between 3 years 18–29 weeks and those examined earlier later or not examined for sex maternal height and age in any of the groups However of those examined during the twelve week period the average birthweight was slightly heavier in the postmature group and the mean gestational age was marginally longer in the small for-dates group Although there was no difference in the distribution of Social Class I–V among those examined in the twelve week period there was a slightly smaller proportion of children with fathers from the Armed Forces in the postmature and random groups there was a slightly smaller proportion of children whose mothers were having their second or third baby in the small for-dates group there was a slightly higher proportion of mothers who came from Northern Ireland among the random and a slightly smaller proportion from the West Indies among the random and twin groups None of these differences was great and only affected proportions of numerically small groups so that they are unlikely to affect the results given here

Minor differences between the proportions of children examined in each of the three four week periods between the ages of 3 years 18–29 weeks were also found for the above variables but again are unlikely to affect the results given here

The analysis

The data has been analysed as three cross sectional studies and as a longitudinal study

(*a*) *Cross sectional studies* Two sample *t* tests were applied to compare the differences in the physical measurements of the three groups from the random sample for boys for girls and for both sexes together The analysis included only children where measurements had not presented difficulties e g refusal to stand still Differences found between the results at the second and third examinations were checked by using only those children examined both times The relation between height and weight was studied using an analysis of covariance

(*b*) *Longitudinal study* The patterns of growth were analysed by dividing the heights and the weights of the children at each examination into quartiles and comparing the differences For birthweight quartiles the standards published by Thomson et al (10) which take into account sex and gestational age up to 42 weeks for singleton children were used For the height and weight quartiles the standards published by Tanner et al (9) which take into account age and sex were used but as figures were given for length only under the age of 2 years heights were extrapolated using the data for 2 years of age where both length and height were given

The data in the longitudinal study refers to a slightly different group of children than that in the cross sectional studies for as the quartiles were standardized for age it was possible to include a wider sample although restricted to those examined on all three occasions

The control group now refers to singleton children with gestational ages of 38–41 weeks (inclusive) who were examined between the ages of 92–109 weeks in the second examination and 3 years 18–29 weeks in the third and where no difficulties were recorded in taking the measurements There was no statistical variation below the 5% level between the quartile distributions of birthweight weight and height for this control group and the standards

To make them compatible the standards for birth weights of singleton children were used for the twins with gestational ages of 38–41 weeks (inclusive)

For postmature children those with gestational ages of 42 and 43 weeks were included but the standards for birthweights of 42 weeks only were used as others were not available

For the small for-dates children those with gestational ages of 38–41 weeks were included The analysis was carried out on both sexes with similar findings but to avoid repetition the results of the longitudinal study are only given for boys

RESULTS

Random sample

Table 1 gives the mean physical measurements of the boys and the girls between the ages of 3 years 18–29 weeks in the third cross sectional study At 94–97 weeks in the second study (2) the boys were significantly heavier than the girls ($p<0\ 001$) and this variation has remained They were still taller but the degree of difference was not so great ($p<0\ 001$ in the second and $p<0\ 01$ in the third) The velocity of growth in height of girls is quicker than that of boys until about the age of 4 years when it is the same for both sexes (9) and this probably accounts for the differences found between the two cross sectional studies

Singleton boys with gestational ages of 4[illegible] and 43 weeks

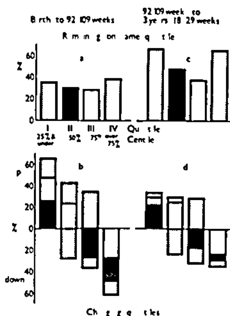

Fig 1 Quartile distributions of weights of singleton boys with gestational ages of 38–41 weeks in the control sample

Fig 1*b* shows that from each quartile the weights of the children were redistributed about the mean for the whole cohort and the degree of redistribution was in much the same order for each quartile

Figs 1*c* and *d* illustrate the changes between 92–109 weeks and 3 years 18–29 weeks 47% and 39% of the children in the two inner quartiles remained unchanged If the movements for the outer quartiles had been of the same order it would be expected that the position of about 70% would have remained unaltered In fact 66% of those in Quartile I and 65% of those in Quartile IV were unchanged Thus again in each quartile the weights were redistributed around the mean with a slightly greater tendency for the lighter and heavier children to alter their position but not to the same extent as in the earlier examination When the results of the three cross sectional studies were considered together the weights of only 19 4% of the boys remained consistently in the same quartile while 17 1% had changed at each examination including 4 6% who showed a steady increase and 2 7% who showed a steady decrease

Length was not recorded at birth so that figures for height are only for the two later examinations (Table 3) when the patterns were similar to those of the weights

Twins

198 or 64 1% of the 309 twins were examined between the ages 3 years 18–29 weeks They were lighter and shorter ($p<0\ 01$) but their body build did not vary significantly from that of the random group so there was no evidence that they had caught up and if anything the gap had widened This was confirmed by repeating the analysis using only those children who had been examined both times Their mean head size was significantly different from that of the random group ($p<0\ 05$) so that on average they had relatively large heads for their bodies

Table 2 shows the quartile distribution of the weights of the 36 male twins The number of fullterm twins is small so figures have not been included as they might have been misleading At birth the weights of almost three quarters were in the first while none were in the fourth quartile By 92–109 weeks considerable movement had taken place and six children had reached the fourth quartile three

of whom had birthweights in the first Between 92–109 weeks and 3 years 18–29 weeks the re distribution was similar to that of the control group in Quartiles I and II but in III and IV only a few children remained unchanged and with one exception those who moved went downwards Ten (28%) of the 36 twins re mained in the same quartile at each examina tion and 12 (33%) were in different ones in cluding 3 (8%) with a steady increase and 1 with a steady decrease

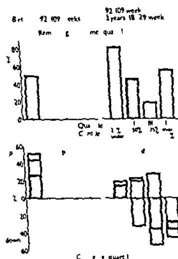

Fig 3 Quartile distributions of weights of singleton boys with gestational ages of 38–41 weeks in the small for dates group (i e on or below the 5th centile)

The distribution and mobility of heights be tween 92–109 weeks and 3 years 18–29 weeks were similar to those of the weights except that at the third examination there was a higher proportion of children in the upper quartiles for height compared with weight (Table 3) An analysis of covariance confirmed that compared with the control group the twins were light for their height

Postmature

Of the 972 postmature children 616 or 63 4% were seen at the third examination Their measurements showed no significant differ ence from those of the random group and whereas they had appeared light for their height at 94–97 weeks they now appeared to be of the same build

Table 2 shows the proportions of the weights of the boys in each of the four quar tiles at the three examinations and Fig 2 il lustrates their distribution and mobility The results were similar to those of the control sample although in the third quartile at 92–109 weeks a smaller proportion moved into the first quartile and a higher proportion into the second compared with the control group The weights of 22 6% of the postmature boys were in the same while 16 8% were in different quartiles at each of the three examinations in

cluding 6 3% who moved up and 4 7% who moved down consistently

Study of the height quartiles gave similar results to those of weight (Table 3)

Small for dates

Of the 799 children 508 or 63 6% were examined These children remained lighter and shorter with smaller head circumference measurements than the random group ($p<0\ 001$) An analysis of covariance showed that individually the children were light for their heights ($p<0\ 001$)

Although all the birthweights of the small for dates boys were in the lower fifth of the first quartile (Fig 3*a*), by the second examination less than half had remained in the first and 7 2% had reached the fourth quartile (Fig 3*b*) At the third examination 81 1% of the boys had remained in the first quartile and whereas between the first two examinations the weight of about half the children had moved upwards between the last two the tendency was to move down rather than up (Figs 3*c* and *d*) Compared with 19 4% of the control sample, 39 5% of the group had not changed quartiles throughout

The distributions of weights and of heights within the quartiles were not significantly different at the second examination At the third, 52% were in the first quartile for weight while the equivalent for height was 44% so that overall the boys appeared to be light for their height In Quartiles I, III and IV there was no significant difference in the proportions who stayed or changed to other quartiles whereas in Quartile II the heights were redistributed to higher quartiles than the weights

DISCUSSION

The results from the two cross sectional studies at birth and at 94–97 weeks of age showed that at the second examination the pattern of distribution of weights was much closer to the normal than that of the birthweights but that differences still remained between the groups selected and the random group (2)

By the age of 3 years 18–29 weeks the differences on average, between the postmature and random groups had disappeared so that if postmaturity had been the cause of fetal malnutrition there is nothing to suggest that it had had a permanent effect on the subsequent physical progress of the children On the other hand, the variations in each of the other groups had persisted and were of the same order as those found at 94–97 weeks Thus although there was considerable evidence of compensation at the second examination this had apparently ceased by the third

By linking the three examinations together the changes could be considered in greater detail Falkner (5) has suggested that once a healthy infant has shaken off the perinatal factors influencing early growth he climbs on to a largely genetically determined series of individual trajectories and then continues along them He considers it takes about 2 years to get 'on target While the above results are generally in agreement with this when the movements from one quartile to another are considered, only a small proportion of the children remained on target from birth to about 3½ years and only about half from about 22 months to 3½ years Thus from birth there was considerable variation in the growth rates of all children with, as might be expected a greater tendency for the weights of the heavier and lighter children to redistribute around the mean As the velocity of growth slowed down the extent of this redistribution tended to lessen but was still taking place at the age of about 3½ years

These findings have strengthened the suggestion in the earlier report (2) that centile charts should be used with caution when monitoring the growth of individual children Large or small children although overall exhibiting hold back or catch up growth are more likely to remain in the same quartiles than those in the middle quartiles and it would seem normal for many children to cross centile lines If

centile charts are used for dietary control (4 6) we would suggest that they should only be used as part of the general assessment of the health of the child taking into account the birthweight and gestational age as well as the height or length It would seem unwise to rely on one or two measurements only

ACKNOWLEDGEMENTS

We wish to thank Professor T E Oppé of St Mary s Hospital Medical School and Professor B Benjamin of City University for their assistance the Medical Research Council for providing the funds the National Birthday Trust Fund for use of the British Births Survey data the doctors who undertook the examinations and the health visitors and administrative staff who traced and found the children

ATOPIC DISEASE IN SEVEN YEAR-OLD CHILDREN

Incidence in Relation to Family History

N I MAX KJELLMAN

From the Department of Paediatrics Linkoping University Linkoping Sweden

ABSTRACT Kjellman N I M (Department of Paediatrics Linkoping University Sweden) Atopic disease in seven year-old children Acta Paediatr Scand 66 465 1977 —The incidence of atopic disease and its relation to the family history was studied by questionnaire in 1325 children 7 years of age A higher incidence of bronchial asthma (2 7%) was found than in a previous Swedish study The total incidence of atopic disease in the children was 15 1% with a higher level when there was a double parental history of such disease (42 9%) as compared with a single such history (19 8%) When both parents had an identical type of atopic disease i e respiratory or skin the incidence of atopic disease was higher (72.2%) than when non identical types occurred in the parents (20.8%) The findings support theories of a polygenic transmission of atopic disease as well as a genetic influence on symptom specificity in such disease and may be of value in genetic counselling

Atopic dermatitis bronchial asthma and allergic rhinitis as well as certain forms of gastrointestinal allergy and urticaria are usually referred to as atopic diseases (18) These diseases show a familial clustering as early as 1650 a familial occurrence of bronchial asthma was reported by Sennertus (23) However there is no agreement about the mode of genetic transmission of the tendency to atopy (2 20 23) The time of onset and the intensity of atopic disease are also decided by genetic (20) and environmental (18) factors

The total incidence of atopic disease in European and North American children is reported to be 12–24% (1 7 16) The incidence of childhood asthma is reported to have increased in the US and the UK in recent decades (15 17) No current data are available on the incidence of atopic disease in Sweden

Children with atopic allergy are more susceptible to infections than others (3) and they also have more respiratory infections and more episodes of otitis media than non atopic children (5)

The present study was initiated by an interest in the actual incidence of atopic disease in Swedish children as well as in the genetic transmission of such disease It seemed of further interest to find out if in fact there is any genetic linkage between a tendency to atopy and recurrent episodes of otitis media

MATERIAL AND METHODS

All 1473 school beginners (7 years of age) in the community of Linköping Sweden were interviewed during 1975 by means of quesionnaire The investigation was coordinated with the usual health survey of the children The questionnaire concerned individual as well as family histories of atopic disease (atopic dermatitis allergic rhinitis allergic urticaria and bronchial asthma) and of recurrent otitis media (defined as otitis media four times or more) The families were also asked to give a short description of possible allergic symptoms in the family members (the school beginner as well as his/her parents

ATOPIC DISLASE IN SEVEN YEAR-OLD CHILDREN

Incidence in Relation to Family History

N I MAX KJELLMAN

From the Department of Paediatrics Linkoping University Linkoping Sweden

ABSTRACT Kjellman N I M (Department of Paediatrics Linkoping University Sweden) Atopic disease in seven year old children Acta Paediatr Scand 66 465 1977.—The incidence of atopic disease and its relation to the family history was studied by questionnaire in 1325 children 7 years of age A higher incidence of bronchial asthma (2 7%) was found than in a previous Swedish study The total incidence of atopic disease in the children was 15 1% with a higher level when there was a double parental history of such disease (42 9%) as compared with a single such history (19 8%) When both parents had an identical type of atopic disease i e respiratory or skin the incidence of atopic disease was higher (72.2%) than when non identical types occurred in the parents (20.8%) The findings support theories of a polygenic transmission of atopic disease as well as a genetic influence on symptom specificity in such disease and may be of value in genetic counselling

Atopic dermatitis bronchial asthma and allergic rhinitis as well as certain forms of gastro intestinal allergy and urticaria are usually referred to as atopic diseases (18) These diseases show a familial clustering as early as 1650 a familial occurrence of bronchial asthma was reported by Sennertus (23) However there is no agreement about the mode of genetic transmission of the tendency to atopy (2 20 23) The time of onset and the intensity of atopic disease are also decided by genetic (20) and environmental (18) factors

The total incidence of atopic disease in European and North American children is reported to be 12–24% (1 7 16) The incidence of childhood asthma is reported to have increased in the US and the UK in recent decades (15 17) No current data are available on the incidence of atopic disease in Sweden

Children with atopic allergy are more susceptible to infections than others (3) and they also have more respiratory infections and more episodes of otitis media than non atopic children (5)

The present study was initiated by an interest in the actual incidence of atopic disease in Swedish children as well as in the genetic transmission of such disease It seemed of further interest to find out if in fact there is any genetic linkage between a tendency to atopy and recurrent episodes of otitis media

tory of atopic disease (Table 2) the incidence of such disease was higher (42 9%) than in the children with a single such heredity (19 8%) in whom however the incidence was higher than in children without any parental history of atopic disease (12 5%) Significantly higher incidences of the 4 studied atopic diseases were also found in children with a double parental history of atopic disease (Table 2) the following p values were found

bronchial asthma	<0 01
allergic rhinitis	<0 01
atopic dermatitis	<0 001
urticaria	<0 05

Comparison of children with a single parental history of atopic disease with those without such history revealed that only atopic dermatitis had occurred more often in the former ($p<0$ 001)

Two or more atopic diseases in the same child occurred more often in those with a double parental history of atopic disease than in any of the other groups (Table 2)

No significant difference was found in the atopy incidence whether a sibling and a parent or only a sibling had atopic disease (*Fig* 2) Rather atopic disease occurred more often with an atopic sibling *than with one* atopic parent ($p<0$ 01)

The incidence of atopic disease in the children was significantly higher ($p<0$ 001) if both parents had an *identical type* of atopic disease i e respiratory or skin (Table 4) than when non identical types occurred in the parents The incidence of atopic disease *in the children* in whom only one parent had a history of atopic disease was significantly higher when the parent had a *combined* type of atopic disease than when there was only one type of such disease in the parent ($p<0$ 01)

Recurrent otitis media was reported to have occurred in 6 5% of the *parents* (*Table 1*) A double parental history of such disease was *found* in 24 (1 8%) of the children (Table 5) and a single such history in 123 children (9 3%) A further 219 children (16 5%) without a parental history of such *disease had* a sibling with recurrent otitis media Thus in all *366 children (27 6%)* had a family history of recurrent otitis media

and siblings) These descriptions were used in the classification of the diseases (atopic or non-atopic)

Answers were received concerning 1325 children (=90 0% of all school beginners) The χ^2 test was used to evaluate group differences

RESULTS

Atopic disease was reported to have occurred in 14 3% of the parents of the 1325 seven year-old children (Table 1) A double parental history of atopic disease was found in 42 of the children (3 2%) and a single such history in 293 (22 1%) of them (Table 2)

In a further 96 children (7 2%)—without parental history of atopic disease—a sibling was reported to have suffered from such disease In all, 431 of the group (32 5%) had a family history of atopic disease

The individual histories of the children in relation to sex are shown in Table 3 Allergic rhinitis and bronchial asthma were reported to have occurred significantly more often in boys than in girls The total incidence of atopic disease was 15 1% with no significant differences between boys and girls The incidence was 24 8% in those with a family history of atopic disease and 10 4% in those without (Fig 1) A family history of atopic disease was reported in 49 5% of the children with such disease The incidence of a positive family history of atopic disease was 73 5% in children with two or more different types of atopic diseases in contrast to 44 6% in children who had only one manifestation of atopic disease ($p<0\ 01$)

In the children with a double parental his

tulsky (2) among others In addition the incidence of a positive family history of atopic disease in the children with atopic disease (49 5%) is in agreement with previous findings (2)

The incidence of a history of bronchial asthma in the children (2 7%) was higher than in a previous Swedish study (1 4% 12) A similar increase has been reported in UK children in recent decades (15) and an even higher incidence (6 3%) of bronchial asthma was found in Australian children (22) Genetic and environmental as well as diagnostic differences may contribute to such discrepancies

The total incidence of atopic disease (15 1%) was similar to incidences reported by Halpern et al (7) in 1973 (12 4% in children from 0 through 7 years of age) and by Rapaport et al (16) in 1960 (19 4% during childhood) In a randomly selected sample of 164 eight year old children (9) 18 3% had a history of atopic disease

Atopic dermatitis is usually the first sign of atopy in childhood—most such cases have their onset in infancy A diagnosis of bronchial asthma is more often made in children 1–6 years of age whilst allergic rhinitis symptoms usually begin between 5 and 19 years of age Hence the total incidence of atopic disease is influenced by the age of the children who are studied It is thus not surprising that the most common disease in the 7 year-old children was atopic dermatitis The higher incidence of allergic rhinitis and bronchial asthma in boys (Table 3) is in accordance with the findings of others (1)

The presence of parental atopic disease was found to be of great importance for the incidence of such disease in the offspring This influence was obvious with regard to the total incidence the type and the intensity of atopic disease in the children

Children with a double parental history of atopy had developed atopic disease twice as often as those with a single such parental history The differences in incidence when both one or no parent was affected indicate a polygenic transmission Similar incidence figures were presented by van Arsdel & Motulsky (2) who also suggested that more than one gene locus must be involved Others have found support for a dominant (20) or recessive autosomal transmission (23) Twin studies (4) do not support any particular type of genetic transmission

In the 18 families in whom the parents had an identical type of atopic disease (i e respiratory or skin type) the toal incidence of atopic disease in the children was high (72 2% Table 4) In all of these families the same disease was found in the parents and the offspring Although this group was small it supports the evidence of a genetic influence on symptom specificity (4 23) The findings may be explained by a genetically determined end organ sensitivity as was recently described by Gerrard et al (6) Turner et al (22) found an additive influence of a biparental disease only in allergic rhinitis but not in bronchial asthma whereas this study favours such an additive influence in both of these repiratory allergies as well as in atopic dermatitis and allergic urticaria

The intensity of atopic disease as measured by the number of symptoms expressed in the

the *children* was 28 0% (Table 5) with the highest incidence in children with a double parental history of such disease (79 2%) and the lowest in those without such a parental history (25 0%)

The incidence of recurrent otitis media in the children was found to be higher ($p<0.05$) in children with a positive parental history of *atopic* disease than in those without However the incidence of recurrent otitis media was similar in the children with (64/200) and without (307/1 125) atopic disease

The duration of breast feeding did not seem to influence significantly the incidence of atopic disease nor the tendency to recurrent otitis media

DISCUSSION

The difficulty of establishing a diagnosis is well known in allergy research (8) The current figures for the incidence of atopic disease which are based on questionnaire data are of course subject to response errors by the parents Even when a child is submitted to a thorough examination and laboratory investigations it may be impossible to categorize the child as allergic or non allergic (11) Probably no such distinct categories exist—rather degrees of atopicity (8) The incidences of atopic disease reported to have occurred in the parents are probably somewhat too low as episodes of atopic dermatitis in infancy (for instance) are misunderstood or even forgotten However nearly identical incidences were reported to have occurred in the parents of the present study and those of 1827 newborns in the same community (9) bronchial asthma 1 9% allergic rhinitis 6 0% atopic dermatitis 7 6% and urticaria 1 7% This similarity suggests that the questionnaire data are valid

The total incidence of a positive family history of atopic disease (32 5%) is supported by the previous findings of van Arsdel & Mo

parents, was also found to influence the incidence of atopic disease in the children in a child with a single parental history of atopic disease the incidence of such disease was significantly higher if the parent had a combined (i e consisting of more than one type of) rather than an isolated atopic disease Also in this respect the twin-data by Edfors Lubs (4) support the present findings

It seems probable that there is a genetic linkage between atopic disease and a tendency to recurrent otitis media as a family history of atopic disease was significantly overrepresented in children with recurrent otitis media Atopic children have more respiratory infections than their siblings or control groups (5, 14) Furthermore atopic individuals have an increased tissue reactivity to vasoactive amines in comparison with others (19) Thus immune responses are more violent in atopic children than in others The infectious swelling of the mucosal membrane is to some extent responsible for the 'asthmatoid character of bronchitis in young children In the upper respiratory tract the Eustachian tube is easily blocked by mucosal swelling and/or cellular infiltrations, and such obstruction predisposes to bacterial infection of the middle ear (13) In accordance with this a high incidence of atopic stigmata has been observed in children with recurrent otitis media and/or recurrent otosalpingitis as well as in children with nasal obstruction and/or repeated respiratory infections (10) Why some atopic children are more apt to nasal or bronchial conditions and others to otological problems may possibly be explained by their different terrain factors which are under a complex genetic influence (21)

In conclusion the incidence of atopic disease was high even before eight years of age in children of two atopic parents and especially high when the same type of allergy occurred in the parents Hence attempts should be made to increase the information given to atopic families (not forgetting the older children) as to the hereditary concept of atopic disease Such information may contribute together with an IgE screening in high risk newborns and an early recognition of a possibly atopic etiology in childhood disease to arrest further increase of atopic disease in childhood

ACKNOWLEDGEMENTS

The author is indebted to Mrs Lena Lindell Mrs Helene Nordahl and Mrs Margit Pettersson for their excellent technical assistance and to the school nurses and the teachers in Linköping for their invaluable help in the collection of data The study was made possible by a generous contribution from Förenade Liv Insurance Company Stockholm and the Medical Faculty Linköping University

parents, was also found to influence the incidence of atopic disease in the children in a child with a single parental history of atopic disease the incidence of such disease was significantly higher if the parent had a combined (i e consisting of more than one type of) rather than an isolated atopic disease Also in this respect the twin-data by Edfors Lubs (4) support the present findings

It seems probable that there is a genetic linkage between atopic disease and a tendency to recurrent otitis media as a family history of atopic disease was significantly overrepresented in children with recurrent otitis media Atopic children have more respiratory infections than their siblings or control groups (5, 14) Furthermore, atopic individuals have an increased tissue reactivity to vasoactive amines in comparison with others (19) Thus immune responses are more violent in atopic children than in others The infectious swelling of the mucosal membrane is to some extent responsible for the ' asthmatoid character of bronchitis in young children In the upper respiratory tract, the Eustachian tube is easily blocked by mucosal swelling and/or cellular infiltrations and such obstruction predisposes to bacterial infection of the middle ear (13) In accordance with this a high incidence of atopic stigmata has been observed in children with recurrent otitis media and/or recurrent otosalpingitis as well as in children with nasal obstruction and/or repeated respiratory infections (10) Why some atopic children are more apt to nasal or bronchial conditions and others to otological problems may possibly be explained by their different terrain factors which are under a complex genetic influence (21)

In conclusion, the incidence of atopic disease was high even before eight years of age in children of two atopic parents and especially high when the same type of allergy occurred in the parents Hence attempts should be made to increase the information given to atopic families (not forgetting the older children) as to the hereditary concept of atopic disease Such information may contribute, together with an IgE screening in high risk newborns and an early recognition of a possibly atopic etiology in childhood disease to arrest further increase of atopic disease in childhood

ACKNOWLEDGEMENTS

ABSTRACT Bläckberg L Hernell O Fredrikzon B and Åkerblom H K (Department of Chemistry Section on Physiological Chemistry Department of Paediatrics University of Umeå Umeå Sweden and Department of Paediatrics University of Oulu Oulu Finland) On the source of lipase activity in gastric contents Acta Paediatr Scand 66 473 1977 —A convenient assay procedure for determination of the activity of pharyngeal lipase (gastric content lipase) using a long chain triglyceride as substrate is described Lipase activity in extracts of rat tongue salivas collected from the upper esophageal pouch from two human newborns with congenital esophageal atresia and in gastric content obtained from an infant with pyloric stenosis were studied Optimal lipase activities of the three enzyme sources were found in the same pH range During hydrolysis the composition of the products formed were also similar The data presented indicate that at least some of the lipase activity which is responsible for lipolysis in the stomach of the newborn originates in pregastric tissues

KEY WORDS Pharyngeal lipase gastric lipolysis esophageal atresia lipid digestion

A few years ago it was shown by Helander & Olivecrona (12) that digestion and absorption of lipids take place in the stomach of the suckling rat This aroused our interest for the possible physiological role of the gastric lipid digestion and also the source and the properties of the lipases involved Lipolytic activity has previously been found in gastric contents from several species i e the rat (4) the dog (8 14) and man (1 6 19) In healthy adult humans the lipase activities were comparatively low and gastric lipolysis was considered to be of minor importance under normal conditions (6) However in a recent study we have found that lipase activity is already present in gastric contents collected at birth and that this lipase activity has properties different from pancreatic lipase (9) The lipase activity in gastric contents was low in the fasting state but increased considerably during a test meal of pasteurized human milk (9) During such a test meal an appreciable amount of the human milk triglycerides are hydrolyzed to mainly diglycerides and fatty acids in the stomach of infants (9 15 16) This suggests that gastric lipolysis might be a physiologically important lipolytic mechanism in the newborn (15 16)

The origin of the lipase responsible for gastric lipolysis is the subject of much controversy Hamosh & Scow (11) recently showed that in the rat serous glands (von Ebner s glands) of the tongue contain a lipase that hydrolyzes triglycerides mainly to diglycerides and fatty acids They suggested that this lipase is responsible for gastric lipolysis in the rat A pregastric esterase which can hydrolyze triglycerides is also present in the pharyngeal tissues of calves (18) In man the source of the gastric lipolytic activity has not been established although a gastric mucosal origin has been suggested (6 19) However recently Ha

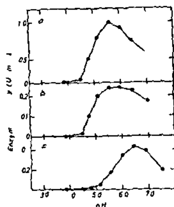

Fig 3 Effect of pH on the lipase activity The incubation system was prepared as described under Methods a 10 µl of enzyme solution (diluted 3 fold) prepared from rat tongue b 10 µl of esophageal aspirate from a human new born with congenital esophageal atresia c 10 µl of gastric contents from an infant with pyloric stenosis

individual tubes The pH value in each tube was recorded after the incubation

One lipase unit is defined as the amount of enzyme that releases 1 µmole of fatty acid per min at 37°C U×ml refers to lipase activity in 1 ml of rat tongue extract esophageal aspirate or gastric content

Determination of the reaction products Incubation mixtures were prepared as above except that tri(9 10(n)-H)-oleylglycerol was substituted for trioleyl(2(n ^{3}H) glycerol (The Radiochemical Centre Amersham England) 700 µl of the incubation mixture were incubated with varying amounts of rat tongue extract esophageal aspirate or gastric content in a total volume of 250 µl Incubation time was 15 min Extraction of lipids and separation of glycerides have been described previously (13)

RESULTS

The use of a radioactive labelled substrate permits accurate determination of very low lipase activities Optimal assay conditions were worked out using a rat tongue extract as enzyme source The amount of fatty acid released was linear with time (Fig 1) and enzyme concentration (Fig 2) until about 100 nmoles had been released into the medium This corresponds to a 10% hydrolysis of the triglycerides Under the conditions used optimal activity of the rat pharyngeal lipase was found in the pH interval 5 0–6 0 (Fig 3*a*)

To study the composition of the products formed during various degrees of hydrolysis different amounts of enzyme were added to the incubation system (Fig 4) For the rat enzyme (Fig 4*a*) there was a rapid release of diglyceride and a much slower release of monoglyceride When the largest amount of enzyme was used diglyceride was still the major partial glyceride found

Identical assay conditions were applied when lipase activity of esophageal aspirates obtained from the two newborns with esophageal atresia and of gastric contents collected from the infant with pyloric stenosis were determined Optimal lipase activity for esophageal aspirate was found in the pH range 5 5–6 5 (Fig 3*b*) and for gastric contents in the interval 6 0–7 0 (Fig 3*c*)

Lipase activities of the esophageal aspirates were 0 5 and 1 3 U×ml^{-1} respectively These activities are of the same magnitude as those found by Hamosh et al in human adults (10) and are in agreement with our previous observation that the ability to synthesize and secrete the pharyngeal lipase is already well developed in the newborn (9) The composition of the products formed during hydrolysis of emulsified triglyceride when either esophageal aspirate or gastric content were as

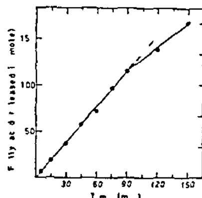

Fig. 1. Time course of the release of fatty acids during incubation with rat pharyngeal lipase. The enzyme solution (prepared as described under Methods) was diluted 6-fold. 10 µl was incubated according to the routine assay procedure.

mosh et al. (10) found lipase activity in esophageal aspirates from healthy adult humans suggesting a pregastric origin also for the human lipase. These authors suggested the name pharyngeal lipase which will be used in the present study.

The aims of the present study were: firstly to develop a convenient procedure for the determination of pharyngeal lipase activity using a long chain triglyceride as the substrate, secondly to find out if the gastric lipolytic activity in the human newborn originates from pregastric tissues and if so, thirdly to compare some properties of the human and the rat pharyngeal lipases.

METHODS

Preparation of enzyme sources. Sprague Dawley rats were killed under light ether anesthesia and the rear part of the tongues including the von Ebner glands were cut off and kept frozen until use. This part of the tongue is rich in lipolytic activity (11, 16). In each preparation 3–4 tongues were used. The tongues were minced with scissors and homogenized in 10 volumes of 0.01 M Tris HCl buffer, pH 8.5, by the use of a Potter Elvehjelm homogenizer. Homogenates were centrifuged for 30 min at 39000 g. The pellets were rehomogenized in 10 volumes of 0.01 M Tris HCl in 1.0 M NaCl, pH 8.5, and then centrifuged as described above. The second supernatant was then used as source of rat pharyngeal lipase.

Two fullterm infants with congenital esophageal atresia were investigated as follows: before operative treatment aspirates of esophageal fluid were collected from the upper esophageal pouch. The aspirates were immediately frozen and stored at −20°C until analyzed. On operation a broncho-esophageal fistula was found in one infant and a tracheo-esophageal fistula in the other. The fluid obtained from the first infant was watery and alcaline, pH 9.0. Where not otherwise stated the aspirate obtained from this infant has been used as the enzyme source in the experiments performed.

Gastric contents were collected from a 25 days old boy suffering from pyloric stenosis. The diagnosis was confirmed on operation. The pH of the sample was 3.6. The sample was centrifuged for 15 min at 12000 g. The clear phase below the upper fatty layer was used as enzyme source.

Assay systems. 2×10^7 cpm of purified (2) tri(9,10(n)-^{3}H)-oleylglycerol (The Radiochemical Centre, Amersham, England) was mixed with 25 mg purified (20) olive oil, 1.0 ml 10% gum arabic, 3.0 ml 0.2 M sodium citrate buffer, pH 6.0, and 2.0 ml distilled water were added. The mixture was cooled with ice-water and sonicated for 4 min at maximal effect in a 100 W-disintegrator (MSE Ltd, London, England). To this emulsion 2.5 ml 18.7% defatted (5) bovine serum albumin (Sigma Chemical Company, St. Louis, Mo., USA), 2.0 ml 3.0 M NaCl and 2.0 ml distilled water were added. The mixture was then equilibrated for 30 min at 37°C. The assay system contained 150 µl of this mixture, enzyme and 0.01 M Tris HCl in 1.0 M NaCl in a total volume of 200 µl. After 15 min preliminary incubation at 37°C in a water bath, the tubes shaking at 50 strokes per minute, the enzyme was added. The reaction was stopped (usually after 15 min) by adding 3.25 ml of a mixture containing methanol, chloroform, heptane 1.41:1.25:1 (v/v/v). 1.0 ml 0.10 M potassium carbonate buffer, pH 10.5, was added (3) and the tubes were vigorously shaken and then centrifuged for 30 min at 1000 rpm in a Sorvall GLC 1 centrifuge (HL-4 rotor). Model experiments showed that 70% of the fatty acid soaps released were extracted into the upper phase. This extraction was not influenced by the various concentrations of NaCl used in the incubation system. 1.0 ml of the upper phase was transferred to a counting vial containing 5 ml Aquasol (NEN Chemicals GmbH, Dreieichenhain, Germany). Radioactivity was determined in a Model 3020 Packard liquid scintillation-spectrometer. When determining the pH optimum of the lipases the buffer of the assay mixture was replaced by distilled water and 40 µl of buffer pH 3.0–7.0 were added to the

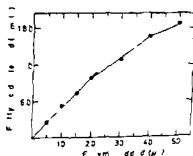

Fig. 2. Effect of the concentration of rat pharyngeal lipase on the amount of fatty acid released. The enzyme solution (prepared as described under Methods) was diluted 10-fold. Varying amounts were incubated in the routine assay system. The incubation time was 60 min.

RESULTS

The use of a radioactive labelled substrate permits accurate determination of very low lipase activities Optimal assay conditions were worked out using a rat tongue extract as enzyme source The amount of fatty acid released was linear with time (Fig 1) and enzyme concentration (Fig 2) until about 100 nmoles had been released into the medium This corresponds to a 10% hydrolysis of the triglycerides Under the conditions used optimal activity of the rat pharyngeal lipase was found in the pH interval 5 0–6 0 (Fig 3*a*)

To study the composition of the products formed during various degrees of hydrolysis different amounts of enzyme were added to the incubation system (Fig 4) For the rat enzyme (Fig 4*a*) there was a rapid release of diglyceride and a much slower release of monoglyceride When the largest amount of enzyme was used diglyceride was still the major partial glyceride found

Identical assay conditions were applied when lipase activity of esophageal aspirates obtained from the two newborns with esophageal atresia and of gastric contents collected from the infant with pyloric stenosis were determined Optimal lipase activity for esophageal aspirate was found in the pH range 5 5–6 5 (Fig 3*b*) and for gastric contents in the interval 6 0–7 0 (Fig 3*c*)

Lipase activities of the esophageal aspirates were 0 5 and 1 3 U×ml⁻¹ respectively These activities are of the same magnitude as those found by Hamosh et al in human adults (10) and are in agreement with our previous observation that the ability to synthesize and secrete the pharyngeal lipase is already well developed in the newborn (9) The composition of the products formed during hydrolysis of emulsified triglyceride when either esophageal aspirate or gastric content were as

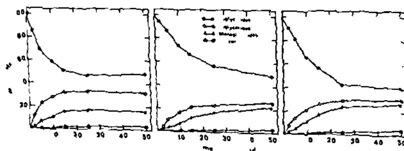

Fig 4 Composition of reaction products formed during hydrolysis of emulsified trioleate The incubations were performed as described under Methods Enzyme sources were varying amounts of (*a*) extract from rat tongue (*b*) esophageal aspirate (*c*) gastric contents

sayed showed great similarities with that obtained during incubation of rat tongue extract (Fig 4*b* and *c*) Thus, there was an initial rapid release of diglyceride and even at 50–60% hydrolysis of the triglyceride diglyceride was the major partial glyceride found This is in contrast to what has been found for the pancreatic lipase (7) In all three experiments there was also only a slow release of glycerol (Fig 4)

DISCUSSION

This study confirms the finding of Hamosh & Scow (11) that rat tongue is rich in a lipolytic activity that hydrolyzes emulsified long chain triglycerides to mainly diglycerides and fatty acids Optimal activity was found between pH 5 0 and 6 0 which is slightly higher than that reported by Hamosh & Scow (11) but the discrepancy may be explained by differences in assay conditions

In man intragastric lipolytic activity has been demonstrated (1 6 19) although the source of the lipase involved has been unknown Recently Hamosh et al (10) found lipase activity in aspirates from esophagus in adults They suggested that the lipase was secreted from pharyngeal tissues In the present study lipase activity was searched for in esophageal aspirates from two newborns with congenital esophageal atresia This should rule out the possibility that the activity could be due to regurgitation of gastro intestinal enzymes The lipase activity found had some properties in common with the lipase from rat tongue Both enzymes had an optimal activity at pH 5 5–6 5 (Fig 3) Furthermore the composition of products formed during hydrolysis of the two enzyme preparations were similar (Fig 4) The lipase activity in gastric contents collected from a newborn with pyloric stenosis to minimize interference due to regurgitation of intestinal lipases had optimal activity in the same pH interval The composition of the products formed during hydrolysis of a long chain triglyceride was also very similar to those found for the lipases from rat tongue and esophageal aspirates (Fig 4) Under the experimental conditions used which may be different from physiological conditions the hydrolysis of an emulsified long chain triglyceride released mainly diglyceride and free fatty acid However also during hydrolysis of milk triglycerides in the stomach of healthy neonates (9) and infants with pyloric stenosis (15 17) diglycerides and free fatty acids are the major products formed

The present data show that in the human infant a lipase is secreted in the digestive tract at a level above the stomach The properties of this lipase are similar if not identical with those of the lipase secreted from the serous glands in the dorsal region of the rat tongue and with those found for the lipase in gastric contents of infants with pyloric stenosis (15) The present data do not necessarily imply that all lipase activity in the gastric contents of the human infant is secreted from the pharyngeal region

The physiological function and importance of the pharyngeal lipase is still unsettled but a tempting hypothesis is that the pharyngeal lipase is mixed with the food already in the mouth and then follows the dietary lipids into the stomach when swallowed In the stomach the lipase catalyzes the hydrolysis of triglycerides to mainly diglycerides and free fatty acids which may be the first step in the digestion of the dietary triglycerides (11 17)

sayed showed great similarities with that obtained during incubation of rat tongue extract (Fig 4*b* and *c*) Thus there was an initial rapid release of diglyceride and even at 50–60% hydrolysis of the triglyceride, diglyceride was the major partial glyceride found This is in contrast to what has been found for the pancreatic lipase (7) In all three experiments there was also only a slow release of glycerol (Fig 4)

DISCUSSION

This study confirms the finding of Hamosh & Scow (11) that rat tongue is rich in a lipolytic activity that hydrolyzes emulsified long chain triglycerides to mainly diglycerides and fatty acids Optimal activity was found between pH 5 0 and 6 0 which is slightly higher than that reported by Hamosh & Scow (11) but the discrepancy may be explained by differences in assay conditions

In man intragastric lipolytic activity has been demonstrated (1 6 19) although the source of the lipase involved has been unknown Recently Hamosh et al (10) found lipase activity in aspirates from esophagus in adults They suggested that the lipase was secreted from pharyngeal tissues In the present study lipase activity was searched for in esophageal aspirates from two newborns with congenital esophageal atresia This should rule out the possibility that the activity could be due to regurgitation of gastro intestinal enzymes The lipase activity found had some properties in common with the lipase from rat tongue Both enzymes had an optimal activity at pH 5 5–6 5 (Fig 3) Furthermore the composition of products formed during hydrolysis of the two enzyme preparations were similar (Fig 4) The lipase activity in gastric contents collected from a newborn with pyloric stenosis to minimize interference due to regurgitation of intestinal lipases, had optimal activity in the same pH interval The composition of the products formed during hydrolysis of a long chain triglyceride was also very similar to those found for the lipases from rat tongue and esophageal aspirates (Fig 4) Under the experimental conditions used which may be different from physiological conditions the hydrolysis of an emulsified long chain triglyceride released mainly diglyceride and free fatty acid However also during hydrolysis of milk triglycerides in the stomach of healthy neonates (9) and infants with pyloric stenosis (15 17) diglycerides and free fatty acids are the major products formed

The present data show that in the human infant a lipase is secreted in the digestive tract at a level above the stomach The properties of this lipase are similar if not identical with those of the lipase secreted from the serous glands in the dorsal region of the rat tongue and with those found for the lipase in gastric contents of infants with pyloric stenosis (15) The present data do not necessarily imply that all lipase activity in the gastric contents of the human infant is secreted from the pharyngeal region

The physiological function and importance of the pharyngeal lipase is still unsettled but a tempting hypothesis is that the pharyngeal lipase is mixed with the food already in the mouth and then follows the dietary lipids into the stomach when swallowed In the stomach the lipase catalyzes the hydrolysis of triglycerides to mainly diglycerides and free fatty acids which may be the first step in the digestion of the dietary triglycerides (11 17)

ROLE OF FEEDING ON LIPASE ACTIVITY IN GASTRIC CONTENTS

B FREDRIKZON and O HERNELL

From the Department of Paediatrics and the Department of Chemistry Section on Physiological Chemistry University of Umea Umea Sweden

ABSTRACT Fredrikzon B and Hernell O (Department of Paediatrics and Department of Chemistry Section on Physiological Chemistry University of Umeå Umeå Sweden) Role of feeding on lipase activity in gastric contents Acta Paediatr Scand 66 479 1977.—Lipase activity was recorded in gastric contents collected from healthy term and preterm neonates In contrast to pancreatic lipase activity this lipase activity was higher at pH 5 5 than at pH 8 0 and it was more resistent to acid inactivation Lipase activity was found in gastric contents from all infants who were regularly fed but was not present in gastric contents from some infants when collected before regular feeding was established During test meals lipase ac tivity in gastric contents increased considerably in all infants studied During such a test meal there was a progressive relative decrease in triglycerides whilst diglycerides showed a relative increase suggesting an active lipolytic process in the stomach An assay procedure for deter mination of lipase activity in gastric contents is also described

KEY WORDS Gastric lipolysis lipase activity pharyngeal lipase lipid digestion neonatal period

Low activities of pancreatic lipase are found in intestinal contents from healthy infants during test meals (16) and intraluminal concentrations of bile acids are lower in infants as compared to adults (16 19) Two essential prerequisites for optimal digestion and absorption of lipids would appear to be incompletely developed at birth Consequently faecal fat excretion is often comparatively high during the first months of life (7) This functional immaturity of the newborn seems paradoxical since in the newborn nearly half of the consumed energy is supplied by dietary lipids (8) and has raised the question as to whether or not other lipolytic mechanisms may contribute to the digestion of lipids in infants (18) In a preliminary report milk lipids were readily hydrolyzed mainly to diglycerides and free fatty acids in the stomachs of infants with pyloric stenosis suggest ing a physiological role of the lipase activity in gastric contents (17)

In the present report gastric contents ob tained from healthy pre and fullterm infants in the fasting state and during test meals were studied This was done to find out if gastric lipase activity is already present at birth and if secretion of the lipase is stimulated by feeding

MATERIALS AND METHODS

Fasting subjects Sixteen infants gestational age (post menstrual) 33–41 weeks were investigated as follows before a scheduled meal a feeding tube was introduced into the stomach and by gentle suction about one ml of gastric contents was collected Samples from 10 subjects were obtained before their first meal The other six in fants had already been fed cow s milk formula pasteur ized human milk or were breastfed

Test meals Six infants gestational age (postmenstrual) 33–37 weeks were at the time for a scheduled feeding given a test meal of pasteurized human milk 20–30 ml/kg body weight Samples of gastric contents were collected before and at intervals during the test meal Lipid com position of gastric contents was analyzed in samples ob tained during one test meal and samples from the others were used for the determination of lipase activities

is easily dispersed in an aqueous medium by mechanical stirring alone and thus there is no need for any exogenous emulsifier Though the substrate itself is practically insoluble in water the liberated butyric acid is readily water soluble During incubations performed according to the standard assay procedure the release of butyric acid was linear with time and enzyme concentration Sometimes a progressive loss of enzyme activity was noted during incubations performed in the absence of bile acids (Fig 1 experiment (c)) However linear kinetics were always obtained when sodium taurocholate was added to the medium (Fig 1 experiment (*d*)) At pH 8 0 virtually no lipase activity was found in gastric contents irrespective of presence or absence of bile acids (Fig 1 experiments (*a*) and (*b*))
Reproducibility of the assay procedure was tested by determination of the lipase activity in one sample on 10 different occasions during a three months period resulting in a mean=32 6 and S D =1 5 (4 6%) Thus lipase activity was unaffected by several freezings and thawings and remained stable at 4°C for hours even at as low a pH as 2 6

Duodenal juice lipase activity at pH 5 5 was always lower than that at pH 8 0 (Fig 2) When the pH of duodenal juice was adjusted to 2 5 virtually all lipase activity was lost within five minutes

Clinical material

Fasting subjects In samples of gastric contents collected from 10 of the 16 infants lipase activity was found All samples from regularly fed infants contained lipase activity as did some samples obtained from non fed infants pHs lipase activities and clinical data are listed in Table 1 All samples lacking lipase activity were obtained from healthy fullterm in

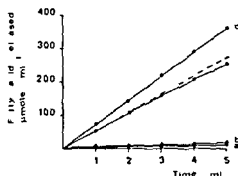

Fig 1 Effect of pH and sodium taurocholate on the amount of butyric acid released 0 05 ml of gastric content (case LT 2 in Table 1) was incubated as follows (*a*) pH 8 0 no bile acid (*b*) pH 8 0 2 5 mM sodium taurocholate (*c*) pH 5 5 no bile acid (*d*) pH 5 5 2 5 mM sodium taurocholate

Duodenal juice Samples of duodenal juice usually about one ml were collected from healthy adults according to the following procedure after an over night fast a doudenal tube was positioned with its tip near the ligament of Treitz under fluoroscopic control The syphoned samples were collected in ice-cooled tubes and immediately frozen

Pyloric stenosis Three infants with pyloric stenosis were investigated On operation the diagnosis was verified in two of the infants No operation was performed on the third infant but X ray findings were characteristic of pyloric stenosis

Laboratory procedures

Lipase activities were determined immediately after sampling or after storage at −20°C Tributyrin (more than 99% pure) *p* nitrophenyl acetate and bovine serum albumin were obtained from Sigma Chemical Company St Louis Mo USA Sodium taurocholate and *p* nitrophenol were of grade A and were supplied by Calbiochem AG Lucerne Switzerland and by Fluka AG Bucks Switzerland respectively

Assay systems

Activity against tributyrin The lipase activity against tributyrin was measured using a Radiometer pH stat equipment (12) The routine incubation medium was prepared as follows 14 5 ml of 0 1 M sodium chloride in 2mM acetate buffer pH 5 5 0 2 ml of a 10% aq solution of sodium taurocholate and 0 5 ml of tributyrin were dispersed in a glass flask (of the type used for liquid scintillation counting) The tributyrin was dispersed in the aqueous phase by magnetic stirring at high speed for about 2 min pH was then adjusted to 5 5 and the consumption of NaOH to maintain pH at 5 5 was recorded for the next 2–5 min As the desired amount of gastric contents usually 0 02–0 2 ml were added an abrupt decrease of pH in the medium occurred which was rapidly compensated for by the automatic addition of NaOH The increase in NaOH required to maintain pH constantly at 5 5 thereafter was considered as the degree of enzyme catalyzed hydrolysis Since the pKa of butyric acid is about 4 8 more than four fifths of the acid is titrated at pH 5 5 No correction factor has been applied for the incomplete titration Incubations were performed in duplicate at 25 C In incubations performed at pH 8 0 the acetate buffer was replaced by a TRIS HCl buffer of the same molarity

Lipase activity in duodenal juice was determined at pH 5 5 and pH 8 0 To obtain linear kinetics 0 1 mg bovine serum albumin was added to the assay system instead of bile acids (1)

Activity against p-nitrophenyl acetate The activity against *p* nitrophenyl acetate was determined according to Erlanson (6) by the use of a Gilford microsample spectrophotometer 300-N The absorbance was continuously registered for 5–10 min after the addition of enzyme Incubations were performed at pH 5 5 and pH 7 4

One enzyme unit is defined as that amount of enzyme that releases 1 µmole of fatty acid or 1 µmole of *p* nitrophenol per minute U×ml⁻¹ refers to enzyme activity of 1 ml of gastric or duodenal juice

Lipid composition The lipid composition of gastric contents collected during one test meal was analyzed as described previously (12)

RESULTS

Laboratory investigations

Lipase activities were determined by continuous titration of fatty acids released from an emulsified substrate This is a simple and accurate method which permits continuous supervision of each determination (1 3 12) Tributyrin was chosen as the substrate because it

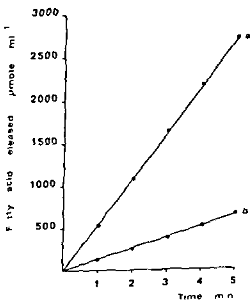

Fig 2 Hydrolysis of tributyrin by duodenal content (*a*) pH 8 0 0 1 mg bovine serum albumin (*b*) pH 5 5 0 1 mg bovine serum albumin 0 008 ml of duodenal content was incubated in each experiment

is easily dispersed in an aqueous medium by mechanical stirring alone and thus there is no need for any exogenous emulsifier Though the substrate itself is practically insoluble in water the liberated butyric acid is readily water soluble During incubations performed according to the standard assay procedure the release of butyric acid was linear with time and enzyme concentration Sometimes a progressive loss of enzyme activity was noted during incubations performed in the absence of bile acids (Fig 1 experiment (c)) However linear kinetics were always obtained when sodium taurocholate was added to the medium (Fig 1 experiment (d)) At pH 8 0 virtually no lipase activity was found in gastric contents irrespective of presence or absence of bile acids (Fig 1 experiments (a) and (b)) Reproducibility of the assay procedure was tested by determination of the lipase activity in one sample on 10 different occasions during a three months period resulting in a mean=32 6 and S D =1 5 (4 6%) Thus lipase activity was unaffected by several freezings and thawings and remained stable at 4 C for hours even at as low a pH as 2 6

Duodenal juice lipase activity at pH 5 5 was always lower than that at pH 8 0 (Fig 2) When the pH of duodenal juice was adjusted to 2 5 virtually all lipase activity was lost within five minutes

Clinical material

Fasting subjects In samples of gastric contents collected from 10 of the 16 infants lipase activity was found All samples from regularly fed infants contained lipase activity as did some samples obtained from non fed infants pHs lipase activities and clinical data are listed in Table 1 All samples lacking lipase activity were obtained from healthy fullterm in

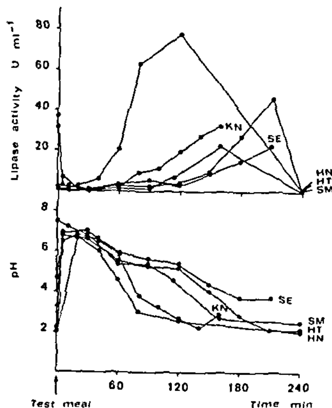

Fig 3 Variation of pH and lipase activities of gastric contents during test meals Samples were collected from infants according to Table 1

into the stomach The other sample was mucous (pH=7 4) and no lipase activity was found (see Table I and Fig 3)

Soon after administration of test meals the pHs of the gastric contents rose to around 6 5 During the following hours the pHs gradually decreased towards values found before the test meals (Fig 3)

The relative molar concentrations of lipids in gastric aspirates during one test meal showed a progressive decrease of triglycerides and an increase mainly of diglycerides (Fig 4) In this particular experiment a molar concentration of about 35% of diglycerides was found 2½ hours after administration of the test meal

Pyloric stenosis All samples from these infants were grossly mixed with milk and the volumes collected were greater than those from healthy infants Lipase activities were found in all samples of gastric contents from these infants (Table I)

fants on their first day of life and before their first meal

Test meals To further study the influence of the feeding process on enzyme activity it was decided to follow the lipase activity of gastric contents during test meals During the meals lipase activities were often initially low but in all infants a considerable increase was found after two to three hours Thereafter lipase activity was again decreased and could not be measured after four hours in three infants (Fig 3) To exclude the possibility of interference from pancreatic lipase activity that might have regurgitated into the stomach those samples containing the highest activities in each subject were assayed both at pH 5 5 and at pH 8 0 At pH 8 0 virtually no lipase activity was found in any of these samples Samples collected from two infants before the test meal were not representative of gastric contents one sample was bile stained (pH=4 7) and at pH 8 0 higher activity was found than that at pH 5 5 suggesting reflux of duodenal contents

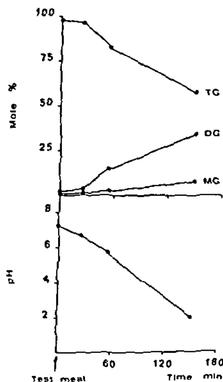

Fig 4 pH of gastric contents and molar composition of glycerides during a test meal procedure Gastric contents were collected at intervals and analyzed as described previously (17) TG DG and MG stand for triglyceride diglyceride and monoglyceride respectively

DISCUSSION

Since regurgitation into the stomach of intestinal juice containing pancreatic lipase activity could not be excluded in the present study it seems justified to discuss briefly some of the characteristics of the pancreatic lipase Pancreatic lipase hydrolyzes dietary triglycerides present in the intestine in an emulsified state essentially to 2 monoglycerides and free fatty acids (2 14) When doudenal juice lipase activity is determined against tributyrin optimal activity is found around pH 8 (3) and considerably lower activities are recorded at pH 5 5 (Fig 2) The activity of pancreatic lipase is rapidly lost at pH 3 or below (5 9) The cholesterol ester hydrolase (pancreatic esterase) (13) is more active against micellar or water soluble substrates e g *p* nitrophenyl acetate (15)

In contrast to samples of gastric contents all samples of duodenal contents showed considerable activity against *p* nitrophenyl acetate

Optimal lipase activity of gastric juice is found around pH 5 5 (4 10) and negligible activities are recorded at pH 8 0 (Fig 1) Diglycerides were the main partial glycerides found during gastric hydrolysis of milk lipids (Fig 4) and similar re ults have been obtained even after extensive hydrolysis of milk lipids or triolein (4 10 11 17)

In infants with pyloric stenosis there should be a reduced risk for duodenal juice reflux into the stomach and thus for contribution of pancreatic lipase activity The gastric juice lipase activities recorded in these infants were however of the same magnitude as those for healthy infants

Thus there are several properties of lipase activity in gastric contents which differ from those of pancreatic and duodenal juice lipase activity This makes it very unlikely that regurgitation of pancreatic lipase activity into the stomach should make a major contribution to lipase activities recorded in gastric aspirates

In fasting subjects lipase activities in gastric contents varied However there was no obvious relation between the clinical condition of the neonate i e gestational age postnatal age birth weight or pH of the gastric aspirate and the lipase activity recorded All samples devoid of lipase activity were collected from healthy fullterm infants on their first day of life before the establishment of a feeding routine However all infants responded to test meals by a considerable increase of lipase activities and in fact the highest value recorded in this study was found in a preterm girl (case HN Fig 3) indicating that the ability to secrete this lipase is already well developed in neonates The stimulatory effect of food was also noted in infants with pyloric stenosis lipase activities comparable to those found in gastric contents from healthy neonates were recorded in these infants despite gross dilution of specimens with partly digested milk A physiological role for this lipase is supported by the increase of lipase activity during the digestive period The relationship between lipase activity and food intake has not been properly recognized in previous reports of gastric juice lipase

The importance of gastric lipolysis in the digestion of lipids is however still uncertain Since milk lipids are readily hydrolyzed by gastric juice lipase but serve as poor substrate for the pancreatic lipase it has been suggested that the importance of gastric lipolysis is limited to the infantile period of life (5) However efficiency of fat digestion is not only a matter of enzyme activities but also of solubilization of the dietary lipids and the lipid products formed It has recently been proposed that the amphiphilic properties of the products formed during gastric lipolysis may facilitate the dispersion and emulsification of dietary lipids (10) If this is true gastric lipolysis may serve as a complement to the normal mechanisms of lipid digestion in two ways

1 By increasing the net hydrolysis of milk lipids

2 By facilitating the dispersion and emulsification of dietary lipids

The first statement gains support in the

In fasting subjects lipase activities in gastric contents varied However there was no obvious relation between the clinical condition of the neonate i e gestational age postnatal age birth weight or pH of the gastric aspirate and the lipase activity recorded All samples devoid of lipase activity were collected from healthy fullterm infants on their first day of life before the establishment of a feeding routine However all infants responded to test meals by a considerable increase of lipase activities and in fact the highest value recorded in this study was found in a preterm girl (case HN Fig 3) indicating that the ability to secrete this lipase is already well developed in neonates The stimulatory effect of food was also noted in infants with pyloric stenosis lipase activities comparable to those found in gastric contents from healthy neonates were recorded in these infants despite gross dilution of specimens with partly digested milk A physiological role for this lipase is supported by the increase of lipase activity during the digestive period The relationship between lipase activity and food intake has not been properly recognized in previous reports of gastric juice lipase

The importance of gastric lipolysis in the digestion of lipids is however still uncertain Since milk lipids are readily hydrolyzed by gastric juice lipase but serve as poor substrate for the pancreatic lipase it has been suggested that the importance of gastric lipolysis is limited to the infantile period of life (5) However efficiency of fat digestion is not only a matter of enzyme activities but also of solubilization of the dietary lipids and the lipid products formed It has recently been proposed that the amphiphilic properties of the products formed during gastric lipolysis may facilitate the dispersion and emulsification of dietary lipids (10) If this is true gastric lipolysis may serve as a complement to the normal mechanisms of lipid digestion in two ways

1 By increasing the net hydrolysis of milk lipids

2 By facilitating the dispersion and emulsification of dietary lipids

The first statement gains support in the

present study for the following reasons the gastric lipase activity is well developed al ready at birth and this lipase activity increases during feeding Finally during digestion of milk in the stomach there is a progressive rel ative decrease of triglycerides and a relative increase of diglycerides, suggesting an active lipolytic process

Although the second statement is more speculative, there are some experimental data supporting this idea (18)

THE FOAM STABILITY TEST ON GASTRIC ASPIRATE IN THE PREDICTION OF RESPIRATORY DISTRESS SYNDROME

M E SPEER A J S CORBET P FLAX and A J RUDOLPH

From the Department of Pediatrics Baylor College of Medicine Texas Medical Center Houston Texas USA

ABSTRACT Speer M E Corbet A J S Flax P and Rudolph A J (Department of Pediatrics Baylor College of Medicine Houston Texas USA) The foam stability test on gastric aspirate in the prediction of respiratory distress syndrome Acta Paediatr Scand 66 485 1977 —To evaluate the usefulness of the foam stability test (FST) on gastric aspirate for predicting respiratory distress syndrome (RDS) in premature infants samples were col lected at delivery or within 30 min from 194 infants ≤36 weeks gestation Of 123 samples adequate for complete testing 44 were positive at 1 2 dilution 43 were positive only at dilu tions <1 2 and 36 were negative at all dilutions RDS was found in 2% 21% and 25% of each group respectively The FST on gastric aspirate at birth gives useful information only if posi tive at 1 2 when a very low incidence of RDS may be expected However a large proportion of infants with FST negative at 1 1 do not develop RDS and hence the test is of limited value in screening for those with highest risk

KEY WORDS Respiratory distress syndrome foam stability test premature infants

The lecithin/sphyngomyelin (L/S) ratio of amniotic fluid described by Gluck (7) has been shown to correlate closely with the development of fetal lung maturity (5 8 13) An alternative procedure is the foam stability test (FST) described by Clements et al (3) which correlates well with the L/S ratio in amniotic fluid and is thought to be useful in the antenatal prediction of the respiratory distress syndrome (RDS) (8 9 10 12 14)

In clinical practice it would be desirable to predict the development of RDS at the time an infant is delivered Borer et al have reported a close correlation between the L/S ratio of fluid aspirated from the infant s stomach and the subsequent development of RDS (2) The present study was designed to evaluate the gastric aspirate FST in the prediction of RDS in premature infants

METHODS

Samples of gastric aspirate were obtained at delivery or within 30 min from 194 infants ≤36 weeks gestation born at Jefferson Davis Hospital in Houston between November 1974 and December 1975 The samples were frozen at −70° centigrade until the FST was performed 1–7 days later

One hundred of the aspirates were tested for foam stability at dilutions of 1 1 1 1 3 and 1 2 by the method of Clements et al (3) A further 94 samples were tested at dilutions of 1 1 and 1 2 but using half the volume of fluid used in the Clements method (6) The results were taken as negative if at the meniscus there were no bubbles visible with the naked eye and positive if any bubbles were visible at the meniscus after standing 15 min

No attempt was made to remove mucus present in the samples but those containing gross blood or meconium were excluded from the study The pH of each sample was determined with pH paper having a range of 3 5–9 0 pH units

To determine whether freezing and storage would effect the FST gastric aspirate was collected from 5 term infants The FST of the pooled sample was positive It was then divided in aliquots frozen at −20°C and the FST

present study for the following reasons the gastric lipase activity is well developed already at birth and this lipase activity increases during feeding Finally, during digestion of milk in the stomach there is a progressive relative decrease of triglycerides and a relative increase of diglycerides suggesting an active lipolytic process

Although the second statement is more speculative there are some experimental data supporting this idea (18)

THE FOAM STABILITY TEST ON GASTRIC ASPIRATE IN THE PREDICTION OF RESPIRATORY DISTRESS SYNDROME

M E SPEER A J S CORBET P FLAX and A J RUDOLPH

From the Department of Pediatrics Baylor College of Medicine Texas Medical Center Houston Texas USA

ABSTRACT Speer M E Corbet A J S Flax P and Rudolph A J (Department of Pediatrics Baylor College of Medicine Houston Texas USA) The foam stability test on gastric aspirate in the prediction of respiratory distress syndrome Acta Paediatr Scand 66 485 1977 —To evaluate the usefulness of the foam stability test (FST) on gastric aspirate for predicting respiratory distress syndrome (RDS) in premature infants samples were collected at delivery or within 30 min from 194 infants ≤36 weeks gestation Of 123 samples adequate for complete testing 44 were positive at 1 2 dilution 43 were positive only at dilutions <1 2 and 36 were negative at all dilutions RDS was found in 2% 21% and 25% of each group respectively The FST on gastric aspirate at birth gives useful information only if positive at 1 2 when a very low incidence of RDS may be expected However a large proportion of infants with FST negative at 1 1 do not develop RDS and hence the test is of limited value in screening for those with highest risk

KEY WORDS Respiratory distress syndrome foam stability test premature infants

The lecithin/sphyngomyelin (L/S) ratio of amniotic fluid described by Gluck (7) has been shown to correlate closely with the development of fetal lung maturity (5 8 13) An alternative procedure is the foam stability test (FST) described by Clements et al (3) which correlates well with the L/S ratio in amniotic fluid and is thought to be useful in the antenatal prediction of the respiratory distress syndrome (RDS) (8 9 10 12 14)

In clinical practice it would be desirable to predict the development of RDS at the time an infant is delivered Borer et al have reported a close correlation between the L/S ratio of fluid aspirated from the infant s stomach and the subsequent development of RDS (2) The present study was designed to evaluate the gastric aspirate FST in the prediction of RDS in premature infants

METHODS

Samples of gastric aspirate were obtained at delivery or within 30 min from 194 infants ≤36 weeks gestation born at Jefferson Davis Hospital in Houston between November 1974 and December 1975 The samples were frozen at −20° centigrade until the FST was performed 1–7 days later

One hundred of the aspirates were tested for foam stability at dilutions of 1 1 1 1 3 and 1 2 by the method of Clements et al (3) A further 94 samples were tested at dilutions of 1 1 and 1 2 but using half the volume of fluid used in the Clements method (6) The results were taken as negative if at the meniscus there were no bubbles visible with the naked eye and positive if any bubbles were visible at the meniscus after standing 15 min

No attempt was made to remove mucus present in the samples but those containing gross blood or meconium were excluded from the study The pH of each sample was determined with pH paper having a range of 3 5–9 0 pH units

To determine whether freezing and storage would effect the FST gastric aspirate was collected from 5 term infants The FST of the pooled sample was positive It was then divided in aliquots frozen at −20°C and the FST

present study for the following reasons the gastric lipase activity is well developed already at birth and this lipase activity increases during feeding Finally during digestion of milk in the stomach there is a progressive relative decrease of triglycerides and a relative increase of diglycerides suggesting an active lipolytic process

Although the second statement is more speculative there are some experimental data supporting this idea (18)

FST is performed substances capable of promoting stable foam are degraded or inactivated this would appear unlikely since our pooled sample showed no change in the positive FST with storage for up to one week

The FST performed on gastric aspirate like that performed on amniotic fluid appears to serve only as a screening procedure for a group of infants with negligible risk of RDS As such it would appear only necessary to perform the test at a dilution of 1 2 because the lesser dilutions give no further useful information The presence of a positive FST on gastric aspirate suggests a diagnosis other than RDS in an infant admitted to the nursery with laboured respiration and such information is obviously important in further assessment There are however a number of serious difficulties in using the gastric aspirate FST which detract from its clinical usefulness Too frequently it is not possible to obtain sufficient sample even for performance of the test at 1 2 dilution This occurred in 23% of cases in the present series of infants Also the number of samples with a positive 1 2 test (23%) was quite small in comparison with the total number of samples obtained Finally a significant number of premature infants 29% in this study can be expected to have a negative test and it can never be stated with certainty which of these infants will develop RDS

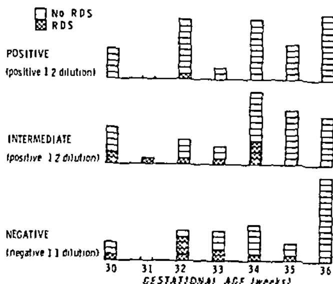

Fig. 1. Relationship of the foam stability test to the diagnosis of respiratory distress syndrome and gestational age.

repeated after thawing at 24, 48, 72 and 168 hours of storage.

The clinical criteria for the diagnosis of RDS were 1) typical diffuse granular densities on the chest radiograph and 2) maximal inspired oxygen greater than 50% (3).

RESULTS

Of the 194 samples collected, 45 (23%) were of insufficient volume to perform the FST. A further 26 (13%) samples had a negative FST at a 1:2 dilution but were of inadequate volume to be tested at lower dilutions. Both of these groups were excluded from the analysis.

Of the 123 samples adequate for an FST, 44 were positive at a dilution of 1:2, 43 were positive only at a dilution <1:2 (intermediate) and 36 were negative at all dilutions. Fig. 1 shows the relationship of the FST to gestational age and the diagnosis of RDS. RDS was found in 2%, 21% and 25% of each group respectively. The incidence of RDS was significantly lower in infants with an FST positive at 1:2 dilution when compared to infants with FST negative at all dilutions or positive only at dilutions <1:2 ($p<0.01$). The incidence of RDS in those with an FST positive at a dilution of <1:2 was similar to that in infants with a negative test.

The gastric aspirate pH of the 123 samples ranged from 3.5 to 8.0 with a mean of 6.7.

In the pooled control sample of gastric aspirate there was no change in the positive FST when tested after freezing for 24, 48, 72 and 168 hours.

DISCUSSION

The pH determinations suggest that gastric aspirate obtained in this study represented amniotic fluid and/or swallowed tracheal fluid and was a suitable fluid for the FST (1).

From the analysis of all investigations carried out so far using amniotic fluid, it can be concluded that a positive FST at 1:2 dilution is associated with an extremely low risk of RDS (3, 8, 9, 10, 12, 14). The present results for the FST in gastric aspirate are in complete agreement because only 2% of infants in our series developed RDS when the FST was positive at 1:2 dilution. In addition, all authors have found that, although intermediate test results in amniotic fluid may correlate well with an intermediate L/S ratio, the development of RDS in this group cannot be predicted with an acceptable degree of accuracy (3, 8, 9, 12, 14). Our results clearly suggest this to be true also of the FST in gastric aspirate.

The data in the literature concerning a negative FST are, however, conflicting. Clements et al., using amniotic fluid, found that a negative test at 1:1 dilution was associated with a very high risk of RDS (3), but others have not found such a close relationship (9, 10, 12, 14). Recently Cowett et al. (4), utilizing the FST performed with gastric aspirate, have suggested there is excellent correlation between a negative FST and the development of RDS. However, our results and those of Evans et al. (6) more closely agree with the majority of workers utilizing the FST on amniotic fluid in that many negative tests were obtained in infants who subsequently did not develop RDS. This finding is consistent with the view that the development of lung maturity occurs prior to the expression of this maturity in the FST on amniotic fluid or gastric aspirate.

An alternative explanation is that before the

FST is performed substances capable of promoting stable foam are degraded or inactivated this would appear unlikely since our pooled sample showed no change in the positive FST with storage for up to one week

EFFECT OF FARLY AND LATE CORD CLAMPING ON THE SYSTOLIC TIME INTERVALS OF THI NEWBORN INFANT

ALICE C YAO and JOHN LIND

From the D partments of Paediatrics Karolinska Institute Stockholm Sweden and Downstate Medical Center State University of New York Brooklyn New York USA

ABSTRACT Yao A C and Lind J (Departments of Paediatrics Karolinska Institute Stockholm Sweden and Downstate Medical Center State University of New York USA) Effect of early and late cord clamping on the systolic time intervals of the newborn infant Acta Paediatr Scand 66 489 1977 —The effect of early and late cord clamping on the left ventricular performance of the newborn infant was assessed by measuring the systolic time intervals from the indirect carotid pulse tracings and simultaneous phonocardiogram and electrocardiogram The study was performed in 13 normal full term infants sequentially at 20–105 min 6–6½ hrs and 24–27 hrs of age The umbilical cords were clamped early in 7 (E C) and clamped late in 6 infants (L C) The ratio of the pre-ejection period (PEP) to the left ventricular ejection time (LVET) was found to be significantly higher in the L C infants (mean±S E 0 400±0 18 0 433±0 018 0 410±0 021) compared with those of the E C (0.334±0 010 0.347±0 009 0.361±0 007) with *p* values of <0 01 <0 005 and <0 05 respec ti ely in the three examination periods This higher PEP/LVET ratios in the L C infants were mainly attributable to a prolongation of the PEP It is suggested that late cord clamping by allowing a sizable placental transfusion appeared to affect adversely the left ventricular performance of the neonate Furthermore it is suggested that in evaluating systolic time intervals of the neonate during the first days of life the volumic state or status of placental transfusion should be taken into consideration as a determinant

KEY WORDS Newborn placental transfusion left ventricular function

The size of placental transfusion is important in the evaluation of the newborn infant in the immediate transitional period after birth be cause of its effects on the circulatory respira tory urinary and other systems of the body (18) It has been shown that by delaying the clamping of the umbilical cord at birth for 3 min or more the blood volume of the infant may be increased by 30% or more Thus the blood volume of the neonate at birth can vary from 77 ml/kg to as much as 120 ml/kg (10) The late-clamped infant adjusts to the larger blood volume by hemoconcentration rapid plasma extravasation and increased urinary output during the first hours of life Consider able differences have been shown in the physiological adaptation to extra uterine life between the early and late clamped infant and no clear cut advantages have been shown in the infant with the larger blood volumes (18) The late-clamped infant was found to sustain a higher systemic blood pressure systemic vascular resistance as well as higher pulmonary artery pressure during the first days of life (1 2 11) The purpose of this study was to determine by a non invasive technique the effect of placental transfusion on the left ventricular function of the newborn infant

MATERIALS AND METHODS

The subjects were 13 normal full term infants of healthy mothers whose pregnancies and deliveries were uncom plicated by any pathology The gestational ages ranged from 37 to 42 weeks weight from 4 0 to 4 750 g Umbili

ences in heart rate QS_2 or LVET The PEP/LVET ratios at all three age periods examined (mean ages 50 min 6 hrs and 24 hours old) showed significantly higher values in the L C group (Mean±S E 0 400±0 18 0 433±0 009) 0 410±0 052 and in the E C group 0 334±0 026 0 347±0 025 0 361±0 007) with p values of <0 01 <0 005 and <0 05 respectively (Fig 2) These elevated PEP/LVET ratios in the L C group were unrelated to the heart rate or LVET but are due to a prolongation of the PEP

The PEP/LVET ratios of both groups are high compared with the adult value of 0 317 given by Weissler et al (16) The ratios of the E C group however appeared fairly similar to those of older infants (6) and those of adults (0 345) as quoted by Braunwald et al (4)

The PEP/LVET ratios within the E C group during the three age periods appeared to have a tendency to increase from the first hour to the sixth hour and more so at the twenty fourth hour Similarly those of the L C group showed some increase at 6 hours of life returning to the initial value by 24 hours These changes are not statistically significant

DISCUSSION

The PEP/LVET ratio derived from the carotid pulse in the normal full term infant during the first 3 days of life had been reported to be 0 390 0 430 and 0 370 respectively (7) These values are slightly lower but fairly close to those of our L C group They are higher than those of the E C group However the time of cord clamping in the newborn was not noted in that report nor in those of others (7 14)

It is interesting to compare our PEP values with those of others using different techniques (Table 3) Using the Doppler Ultrasound the average PEP in term fetuses during labour were 70 ms and 73 ms (9 13) These values are very close to those of our E C infants which may overlap the upper limits of normal in adults By echocardiographic technique the

PEP of the left ventricle was found to range from 60 to 95 ms during the first day of life (15) Although the time of cord clamping was not known in the latter study the PEP values as well as the PEP/LVET ratios spanned a range corresponding those of our E C and L C infants These authors noted that 20% of their cases have the higher values similar to those of our L C group These values in the newborn infant are by and large higher than those of older infants and adults (4 6 16) suggesting strained left ventricular function

The blood volume of the fetus at term (17) is about that of the E C infant (18) The increase in blood volume after late cord clamping is sizable and abrupt This usually occurred in an arbitrary manner at birth In no other situation in life does this physiologic phenomenon occur in such an abrupt manner that a transfusion of as much as 100 ml of blood can occur within 3 minutes to a 3½ kg infant Its physiologic consequences on the neonate s early extra uterine adaptation was shown to be significant The L C infant appeared to take a longer time and exert more effort to achieve extra uterine adjustment especially in its cardiorespiratory

Table 1 *Clinical data of newborn infants studied*

Group	No of cases	Body weight (g) Mean±S D	Length (cm) Mean±S D	Time of cord clamping Mean
I	7	3 451 4±562	50 6±1 8	1 5 sec
II	6	3 503 3±632	50 5±2 3	4 min

cal cords were clamped early (E C) at 1–3 sec after birth in 7 and clamped late (L C) at 3–5 min in 6 infants (Table 1) Simultaneous electrocardiogram (ECG) phonocardiogram (PCG) and indirect carotid pulse traces (CP) were recorded in each infant sequentially at 20–105 min 6–6½ hrs and 24–27 hrs of life The infants were warmly clad and room temperature kept constant within the range 26 5 to 28 5 C The CP was recorded by an arterial pulse receptor made of plastic connected to an Elema Schönander EMT510C transducer (0 5–30 Hertz frequency response) by an air filled tube The receptor was placed gently over the infant s carotid area with its head slightly turned to the opposite side and in mild extension Tracings were made after oscilloscopic display of the CP were noted to be stable and acceptable at a paper speed of

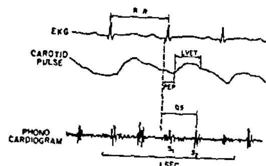

Fig 1 Simultaneous recordings of lead II ECG phonocardiogram and carotid pulse showing how the different systolic time intervals are measured

100 mm/sec in an Elema Schonander Mingograf 81 An EMT 25 microphone was used for the PCG recording over the lower left sternal border and lead II ECG taken by standard technique

Systolic time intervals (STI) were measured as follows (Fig 1) (i) electromechanical systole (QS_2) from the onset of QRS complex to the first high frequency deflection of second heart sound (ii) left ventricular ejection time (LVET) from the beginning of the upstroke of carotid pulse to the dicrotic notch (iii) pre-ejection period (PEP) derived by subtracting LVET from QS_2 thereby eliminating the delay in transmission of the arterial pulse to the carotid artery The PEP/LVET ratio was then calculated The R R interval from the ECG was measured for heart rate The average of 10–15 heart beats was analysed for each period of study in each infant

RESULTS

A significantly longer PEP was noted in the L C group than in the E C group from birth to 6 hours and almost through 24 hours of life (Table 2) There were no significant differ

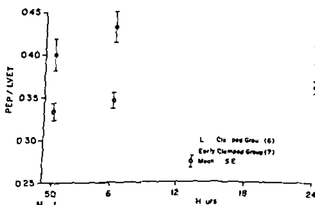

Fig 2 Mean PEP/LVET ratios of 7 early-clamped and 6 late-clamped full term infants showing significant differences at less than an hour of life ($p<0.01$) at 6 hours ($p<0.005$) and at 24 hours ($p<0.05$)

ences in heart rate QS_2 or LVET The PEP/LVET ratios at all three age periods examined (mean ages 50 min 6 hrs and 24 hours old) showed significantly higher values in the L C group (Mean±S E 0 400±0 18 0 433±0 009) 0 410±0 052 and in the E C group 0 334±0 026 0 347±0 025 0 361±0 007) with p values of <0 01 <0 005 and <0 05 respectively (Fig 2) These elevated PEP/LVET ratios in the L C group were unrelated to the heart rate or LVET but are due to a prolongation of the PEP

The PEP/LVET ratios of both groups are high compared with the adult value of 0 317 given by Weissler et al (16) The ratios of the E C group however appeared fairly similar to those of older infants (6) and those of adults (0 345) as quoted by Braunwald et al (4)

The PEP/LVET ratios within the E C group during the three age periods appeared to have a tendency to increase from the first hour to the sixth hour and more so at the twenty fourth hour Similarly those of the L C group showed some increase at 6 hours of life returning to the initial value by 24 hours These changes are not statistically significant

DISCUSSION

The PEP/LVET ratio derived from the carotid pulse in the normal full term infant during the first 3 days of life had been reported to be 0 390 0 430 and 0 370 respectively (7) These values are slightly lower but fairly close to those of our L C group They are higher than those of the E C group However the time of cord clamping in the newborn was not noted in that report nor in those of others (7 14)

It is interesting to compare our PEP values with those of others using different techniques (Table 3) Using the Doppler Ultrasound the average PEP in term fetuses during labour were 70 ms and 73 ms (9 13) These values are very close to those of our E C infants which may overlap the upper limits of normal in adults By echocardiographic technique the PEP of the left ventricle was found to range from 60 to 95 ms during the first day of life (15) Although the time of cord clamping was not known in the latter study the PEP values as well as the PEP/LVET ratios spanned a range corresponding those of our E C and L C infants These authors noted that 20% of their cases have the higher values similar to those of our L C group These values in the newborn infant are by and large higher than those of older infants and adults (4 6 16) suggesting strained left ventricular function

The blood volume of the fetus at term (17) is about that of the E C infant (18) The increase in blood volume after late cord clamping is sizable and abrupt This usually occurred in an arbitrary manner at birth In no other situation in life does this physiologic phenomenon occur in such an abrupt manner that a transfusion of as much as 100 ml of blood can occur within 3 minutes to a 3½ kg infant Its physiologic consequences on the neonate s early extra uterine adaptation was shown to be significant The L C infant appeared to take a longer time and exert more effort to achieve extra uterine adjustment especially in its cardiorespiratory

system as reviewed by us (18) Our finding of a significantly higher PEP/LVET in the L C than E C infants suggested that the volemic state at birth is an important factor which influences the STI in the newborn It appeared that late clamping of the umbilical cord which effected a sizable placental transfusion adversely affects the already somewhat strained left ventricular function of the newborn infant

A prolongation in the PEP accompanying abnormal fetal heart rate pattern had been recorded in human term fetuses in distress by Doppler cardiogram (9) Experiments in fetal lambs showed prolongation of the PEP upon occlusion of the cord and a shortening on its release (12) This change was ascribed to change in arterial pressure The high PEP/LVET ratio in the L C infants was due mainly to the prolongation of the PEP suggesting that this might be due to an increase in the afterload on the heart The systemic blood pressure has been observed to be higher in the L C than in the E C infants during the first 6 hours of life and the systemic vascular resistance likewise during the first day (1 11) However the diastolic arterial pressure needed to be measured in both E C and L C infants The rapid hemoconcentration observed in the L C infants (10 18) may have contributed to the increase in afterload on the heart The transiently higher left atrial pressure in the L C infant (3) may have increased the preload on the heart which should have increased stroke volume and LVET and decreased PEP Instead the opposite effect on the STI was seen in the L C infants suggesting that either the preload increase is too transient and insignificant because of rapid plasma extravasation or that there is an inherent contraction limit in neonatal myocardium Structural and functional studies of fetal and neonatal myocardium in lambs suggested the existence of such an inherent limitation (5 8) It is possible that the newborn myocardium in the human infant may have similar characteristics which limits its capacity to respond to an increased blood volume

EFFECT OF AGE ON HUMAN ADIPOSE TISSUE METABOLISM AND HORMONAL RESPONSIVENESS

G NYBERG A HAGER and U SMITH

From the Department of Medicine II Sahlgren s Hospital University of Gothenburg and the Department of Paediatrics University Hospital Linkoping Sweden

ABSTRACT Nyberg G Hager A and Smith U (Department of Medicine II Sahlgren s Hospital University of Gothenburg and Department of Paediatrics University Hospital Linkoping Sweden) Effect of age on human adipose tissue metabolism and hormonal responsiveness Acta Paediatr Scand 66 495 1977.—The effects of age and fat cell size on the metabolism of white human adipose tissue were analysed independently Abdominal subcutaneous adipose tissue specimens were obtained from children varying in age from 0–15 years and from adults (mean age±S D 38.2±14 1 years) The basal rates of lipolysis and glucose incorporation into lipids were considerably higher in children than in adults even when differences in fat cell size had been taken into account Lipolysis in response to a maximal concentration of noradrenalin was higher in fat cells from children However on a percentage basis the responsiveness to this agent was similar in children and adults Irrespective of age glucagon did not elicit a lipolytic response Thus it does not seem that the increased lipolysis known to occur *in vivo* in the neonatal period is due to a direct effect of glucagon on white adipose tissue However the overall lipolytic capacity is increased in fat cells from children

KEY WORDS Fat cell metabolism age lipolysis glucagon catecholamines

The human infant obtains a large part of its energy requirements from fatty acids mobilized from both brown and white adipose tissue (24 28) Novak et al (22) have shown that lipid mobilization from white adipose tissue is particularly high during the first hours after birth and then declines rapidly During infancy the lipolytic rate is only slightly higher than in adults (22) This interpretation is however somewhat hampered by the fact that fat cell size of white adipose tissue increases rapidly during the first year of life (15 23) A tissue with a small fat cell size contains a larger number of fat cells per unit weight than a tissue with larger cells Since the data of Novak et al (22) were expressed per unit tissue weight rather than in terms of the cellularity the metabolic rates may be misleading

In a recent study on rat tissue the effects of fat cell size and age on adipocyte metabolism were analysed independently (14) It was found that irrespective of cell size the metabolic rates were considerably increased in the younger animals A pronounced difference in the cellular responsiveness to glucagon was found in that fat cells from young animals responded briskly to glucagon while adipocytes from older animals were glucagon resistant (14 21) These findings are in agreement with a recent report by Cooper & Gregerman (7) showing a decline in glucagon stimulated adenylate cyclase activity with age in rat fat cells

It is well-established that adult human fat cells respond only sluggishly (2) or not at all to the lipolytic effect of glucagon *in vitro* (5) In

view of the findings discussed above it may well be then that fat cells from young individuals are reponsive to glucagon Since glucagon levels are elevated in newborns (20) it seems of importance to evaluate the possible physiological significance of this agent for lipid mobilization

In the present investigation glucose incorporation and basal and stimulated lipolysis were evaluated in human adipose tissue with respect to both fat cell size and age

MATERIALS AND METHODS

Biopsies of abdominal subcutaneous adipose tissue were obtained from 32 children varying in age from a few hours up to 15 years The children were generally operated upon for inguinal hernia or retained testis Two newborns were included who were operated upon for esophagus atresia or an ovarian cyst The metabolic responses of fat cells from children were compared with the results obtained with abdominal subcutaneous fat from adults who were selected so as to have similar fat cells sizes as the children The adults were operated upon for cholecystolithasis (1) gastric ulcer (2) varicocele (3) ovarian cyst (2) renal stones (1) or a hyperplastic prostate (1)

After excision smaller biopsies weighing about 20–30 mg each were prepared and preincubated for 30 min in the same medium as was later used for the incubations The biopsies were then placed in fresh medium and incubated for 2 hrs at 37 C The incubation medium used was medium 199 (Statens Bakteriologiska Laboratorium Stockholm) modified to a glucose concentration of 1 0 mM containing 40 g/l bovine albumin (Fraction V Sigma Chemical Co St Louis Mo) and the indicated concentrations of noradrenalin (noradrenalin bitartrate Astra AB Sodertalje Sweden) or glucagon (Novo A/S Copenhagen) In some experiments 0 15 μCi [1 ^{14}C]glucose (New England Nuclear Corp Frankfurt/Main W Germany) was added to the incubation medium and the incorporation into the triglycerides determined The release of glycerol to the incubation medium was determined enzymatically (19) and taken as an index of lipolysis

After the incubation period the tissue lipids were extracted with chloroform/methanol (2 1 v/v) as described by Folch et al (9) An aliquot of the chloroform phase was taken for the determination of the radioactivity in the triglycerides using a Packard Tri-Carb liquid scintillation spectrometer (Packard La Grange Illinois) Glyceride glycerol was determined on the chloroform phase as described by Carlson (6) After saponification the fatty acids were in some experiments extracted with *n* heptane and the radioactivity determined

The metabolic parameters studies were expressed in terms of the cellularity of the specimens as previously suggested (1 12 25) *Fat cell size was determined after* isolation with collagenase as previously described (27) The amount of collagenase used was the same for both children and adults 5 mg per 3 ml medium The error of the sizing procedure used has been found to be 3 4% (27) Mean cellular volume was calculated as described by Goldrick (10) and mean cellular weight according to Hirsch & Gallian (13) assuming that the density of fat cells equals that of triolein When the triglyceride content of the biopsies and the mean cellular weight are known *the number of fat cells can be calculated*

Since adipocyte size is an important parameter for metabolic rates (1 16 17 25 29) the measured parameters were related to fat cell surface area calculated from the measured diameters as described by Zinder & Shapiro (29)

RESULTS

The subjects were divided into four groups of equal size according to the age of the donors (below 1 yr 1–4 yrs, 5–15 yrs and adults= 38 2±14 1 years mean ±S D)

Cell size

The correlations between basal lipolysis basal rate of glucose incorporation into triglycerides and cell surface area were significant for both adults and children between 5 and 15 years (*r* values between 0 581 and 0 828 $p<0\ 05$) For the children below 1 year and between 1–4 years however the correlation coefficients did not reach statistical significance

Age

Since cell size influenced the rates of metabolism this factor had to be eliminated in order to analyse the effect of age This was performed by multivariate analysis with weighted means (18) As shown in Table 1 adults had lower rates of glucose incorporation and basal *and stimulated lipolysis than the children* The differences were highly significant for all parameters measured for children in the two oldest age groups For the youngest children however only a tendency to a difference ($p<0\ 10$) was found for glucose incorporation

Between the three child groups there were no significant differences in the parameters measured except that basal lipolysis was lower in the youngest group *In this group one* specimen was obtained *from a child within 24* hrs after birth and in another child after 120

		<0 10 (<1 vs adults)			

Statistical calculations performed with multivariate analysis with weighted means (18) This method eliminates the effect of cell size (cell surface) on metabolism and permits analysis of the relations between age and metabolism

[a] Mean ±S D weighted means

[b] No further testing since $n=1$

hrs The basal lipolysis of the specimen from the newborn child was the highest in this group (112 6 nmoles/10[5] cells) while the specimen taken after 120 hrs was within the range of the other children (21 5 nmoles/10[5] cells)

Hormonal responsiveness

In contrast to glucagon (see below) noradrenalin consistently enhanced lipolysis in all age groups As shown in Table 1 the lipolytic rate was significantly higher in the child specimens than in the adults Due to the rather small biopsy samples obtained only one experiment with noradrenalin was performed with fat cells from a child below 1 yr of age (4 months) However this specimen responded briskly (Table 1) Although the lipolytic rates in response to noradrenalin were higher in the child groups the percentage increases over basal values were similar in both adults and children

Addition of glucagon at a high concentration did not elicit a consistent lipolytic effect in any child group (Table 2) Similarly no effect of glucagon on glucose metabolism was found in either child group (data not shown)

DISCUSSION

The present study was undertaken to analyse the effect of age on metabolism The data show that fat cell size is of importance for the

view of the findings discussed above it may well be then that fat cells from young individuals are reponsive to glucagon Since glucagon levels are elevated in newborns (20) it seems of importance to evaluate the possible physiological significance of this agent for lipid mobilization

In the present investigation, glucose incorporation and basal and stimulated lipolysis were evaluated in human adipose tissue with respect to both fat cell size and age

MATERIALS AND METHODS

Biopsies of abdominal subcutaneous adipose tissue were obtained from 32 children varying in age from a few hours up to 15 years The children were generally operated upon for inguinal hernia or retained testis Two newborns were included who were operated upon for esophagus atresia or an ovarian cyst The metabolic responses of fat cells from children were compared with the results obtained with abdominal subcutaneous fat from adults who were selected so as to have similar fat cells sizes as the children The adults were operated upon for cholecystolithiasis (1) gastric ulcer (2) varicocele (3) ovarian cyst (2) renal stones (1) or a hyperplastic prostate (1)

After excision smaller biopsies weighing about 20–30 mg each were prepared and preincubated for 30 min in the same medium as was later used for the incubations The biopsies were then placed in fresh medium and incubated for 2 hrs at 37 C The incubation medium used was medium 199 (Statens Bakteriologiska Laboratorium Stockholm) modified to a glucose concentration of 1 0 mM containing 40 g/l bovine albumin (Fraction V Sigma Chemical Co St Louis Mo) and the indicated concentrations of noradrenalin (noradrenalin bitartrate Astra AB Sodertalje Sweden) or glucagon (Novo A/S Copenhagen) In some experiments 0 15 μCi [1 ^{14}C]glucose (New England Nuclear Corp Frankfurt/Main W Germany) was added to the incubation medium and the incorporation into the triglycerides determined The release of glycerol to the incubation medium was determined enzymatically (19) and taken as an index of lipolysis

After the incubation period the tissue lipids were extracted with chloroform/methanol (2 1 v/v) as described by Folch et al (9) An aliquot of the chloroform phase was taken for the determination of the radioactivity in the triglycerides using a Packard Tri-Carb liquid scintillation spectrometer (Packard La Grange Illinois) Glyceride glycerol was determined on the chloroform phase as described by Carlson (6) After saponification the fatty acids were in some experiments extracted with *n* heptane and the radioactivity determined

The metabolic parameters studies were expressed in terms of the cellularity of the specimens as previously suggested (1 12 25) Fat cell size was determined after isolation with collagenase as previously described (27) The amount of collagenase used was the same for both children and adults 5 mg per 3 ml medium The error of the sizing procedure used has been found to be 3 4% (27) Mean cellular volume was calculated as described by Goldrick (10) and mean cellular weight according to Hirsch & Gallian (13) assuming that the density of fat cells equals that of triolein When the triglyceride content of the biopsies and the mean cellular weight are known the number of fat cells can be calculated

Since adipocyte size is an important parameter for metabolic rates (1 16 17 25 29) the measured parameters were related to fat cell surface area calculated from the measured diameters as described by Zinder & Shapiro (29)

RESULTS

The subjects were divided into four groups of equal size according to the age of the donors (below 1 yr 1–4 yrs 5–15 yrs and adults= 38 2±14 1 years mean ±S D)

Cell size

The correlations between basal lipolysis basal rate of glucose incorporation into triglycerides and cell surface area were significant for both adults and children between 5 and 15 years (r values between 0 581 and 0 828 $p<0$ 05) For the children below 1 year and between 1–4 years however the correlation coefficients did not reach statistical significance

Age

Since cell size influenced the rates of metabolism this factor had to be eliminated in order to analyse the effect of age This was performed by multivariate analysis with weighted means (18) As shown in Table 1 adults had lower rates of glucose incorporation and basal and stimulated lipolysis than the children The differences were highly significant for all parameters measured for children in the two oldest age groups For the youngest children however only a tendency to a difference ($p<0$ 10) was found for glucose incorporation

Between the three child groups there were no significant differences in the parameters measured except that basal lipolysis was lower in the youngest group In this group one specimen was obtained from a child within 24 hrs after birth and in another child after 120

Statistical calculations performed with multivariate analysis with weighted means (18) This method eliminates the effect of cell size (cell surface) on metabolism and permits analysis of the relations between age and metabolism

[a] Mean ±S D weighted means

[d] No further testing since $n = 1$

hrs The basal lipolysis of the specimen from the newborn child was the highest in this group (112 6 nmoles/10[5] cells) while the specimen taken after 120 hrs was within the range of the other children (21 5 nmoles/10[5] cells)

Hormonal responsiveness

In contrast to glucagon (see below) noradrenalin consistently enhanced lipolysis in all age groups As shown in Table 1 the lipolytic rate was significantly higher in the child specimens than in the adults Due to the rather small biopsy samples obtained only one experiment with noradrenalin was performed with fat cells from a child below 1 yr of age (4 months) However this specimen responded briskly (Table 1) Although the lipolytic rates in response to noradrenalin were higher in the child groups the percentage increases over basal values were similar in both adults and children

Addition of glucagon at a high concentration did not elicit a consistent lipolytic effect in any child group (Table 2) Similarly no effect of glucagon on glucose metabolism was found in either child group (data not shown)

DISCUSSION

The present study was undertaken to analyse the effect of age on metabolism The data show that fat cell size is of importance for the

Table 2 *Lipolysis in response to glucagon in fat cells from donors of varying age (expressed in nmoles/10⁵ cells)*[a]

metabolic rates at least in older children and adults Since fat cell size varies with the degree of obesity (3) as well as the age of the donor (15, 23) this factor must be considered when the relationships between age and metabolism are evaluated In the present study this objective was reached in two ways Firstly the adults were selected so that their fat cell sizes were within the same range as the children Secondly in the statistical analyses the effects of fat cell size and age on metabolism were analysed independently The data show that the basal rates of lipolysis and glucose incorporation were higher in the children than in the adults Less pronounced differences were found for the children below one year of age, however Although we have very few data on metabolism in the immediate neonatal period the data support the findings of Novak et al (22) i e that the fat cells have an exceedingly high lipolytic rate in this period The main discrepancy between that study and the present one is our finding that the rate of lipolysis is considerably higher throughout childhood as compared with adults while Novak et al (22) found only a slight difference after the neonatal period This discrepancy may however be due entirely to the fact that possible differences in fat cell size were not accounted for in their study

Lipolysis in response to noradrenalin was higher in children than in adults when expressed as an absolute effect However on a percentage basis the increase was similar in all age groups It should be emphasized that in the present study a maximal concentration of noradrenalin was used Thus the increased absolute lipolytic effect means that the cellular *capacity is increased In order to evaluate* possible differences in cellular *sensitivity dose–response curves should be performed* (17) Due to the smallness of the tissue specimens usually obtained this was not possible in the present study

Of particular interest was the finding that glucagon failed to elicit a lipolytic response at any age It is well known that adult human adipose tissue responds only sluggishly (2) or not at all to this hormone (5) However in view of previous data showing that young rats are responsive to glucagon in contrast to old animals (14, 21) and that glucagon induced adenylate cyclase activity declines with age (7) an effect of glucagon on child adipose tissue could have been anticipated Since lipolysis seems particularly high immediately after birth as discussed above (24 28) and since glucagon levels are elevated after birth (20) such an effect would have had physiological implications From the present study however it seems clear that the increased lipolysis after birth is not due to a direct effect of glucagon on white fat cells The reason for this lack of effect of glucagon on human fat cells is not clear Since an effect of glucagon on glucose metabolism (known from other studies with rat fat cells (4)) was lacking as well this glucagon resistance may be due to a lack of membrane hormonal receptors

In analogy with the effect of age on lipolysis the rate of glucose conversion to triglycerides is also increased in the children Since adult human adipose tissue only synthesizes fatty acids to a very small extent (26) incorporation into total lipids was usually determined From studies on rat fat cells however it has been found that fatty acid synthesis decreases with increasing age (8) As shown in four control experiments about 20% of the total glu

cose uptake is recovered in the fatty acid moiety in child fat cells as compared with about 5% in adults (26) Thus the increased rate of glucose incorporation into the trigly cerides is due to an increase in the synthesis of both fatty acids and glyceride glycerol

The present evidence of increased basal lipolysis throughout childhood is somewhat at variance with a previous report (23) in which the authors using a tissue culture technique found that basal lipolysis was consistently higher only in fat cells from children below one year of age The reason for this discrepancy is presumably the difference in incubation tech niques used With the tissue culture technique the effects of host factors are presumably eli minated and a more basal state is reached than in the present short term incubations It may well be then that the increased meta bolic rates in child adipose tissue as compared with adults are primarily associated with exo genous factors such as differences in hormone levels (cf 11 20) and/or nutritional differences

ABSTRACT Higurashi M Segawa M Matsui I Ihnuma K and Nakagome Y (Department of Maternal and Child Health and Department of Pediatrics University of Tokyo Tokyo Division of Medical Genetics Kanagawa Children s Medical Center Yokohama Department of Human Genetics National Institute of Genetics Mishima Japan) Screening for autosomal aberrations Acta Paediatr Scand 66 501 1977 —A method of screening for autosomal aberrations is important as an indication for chromosome analysis such as that used in sex-chromatin examination for sex chromosome aberrations In our clinic malformed patients with mental retardation and abnormal dermatoglyphic patterns are strong suspects for autosomal aberrations Abnormal dermatoglyphic patterns are separated into two categories (1) Absolutely abnormal—radial loop of 1st finger radial loop of 4th finger radial loop of 5th finger arch over 6 fingers arch tibial loop tibial and arch fibular (2) Borderline abnormalities—high axial triradius (t and t'') simian crease interdigital loop and single crease of 5th finger Of 416 cases showing malformation retardation and abnormal dermatoglyphics 308 had autosomal aberrations while 108 had normal karyotypes In the group with autosomal aberrations 279 patients (90 6%) had absolutely abnormal dermatoglyphics In the group with normal karyotypes only 8 patients (7 4%) had absolutely normal dermatoglyphics while most had abnormal dermatoglyphics in the borderline category These clinical manifestations absolutely abnormal dermatoglyphics mental retardation and malformations are therefore very useful in screening for autosomal aberrations

KEY WORDS Screening autosomal aberrations dermatoglyphics

The rapid development of human cytogenetics during the past twenty years and the discovery of numerous human cytogenetic abnormalities have opened up new aspects of both human genetics and teratology (3 7 9) Cytogenetics laboratories may be asked to carry out chromosome investigations on individuals with congenital malformations but it is not yet feasible for all patients with malformations to be examined by chromosome analysis Some tools for the screening of autosomal aberrations if there were any such would be useful in the selection of indications for this examination such as sex-chromatin examinations as a screening method for sex chromosome aberrations (2 6)

Malformed patients with mental retardation and abnormal dermatoglyphic patterns attending our clinic have been suspected strongly of autosomal aberrations for these ten years All cases with the above Triad Congenital malformations mental retardation and abnormal dermatoglyphic patterns have undergone cytogenetic examinations and it has been found that these clinical manifestations are useful in screening for autosomal aberrations

This work was partly aided by a grant from the Ministry of Health and Welfare Japan

MATERIALS AND METHODS

The study included 416 patients with multiple malformations mental retardation and abnormal dermatoglyphics who attended the Malformation Clinic and Neurology

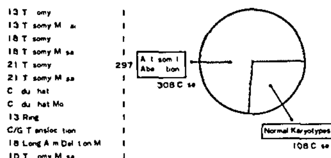

Fig 1 Materials

Clinic Department of Pediatrics University Hospital at the University of Tokyo The patients were of both sexes and all were younger than 15 years of age Abnormal dermatoglyphic patterns in Japanese as shown by Matsui et al (4) were separated into two categories (1) absolute abnormalities—radial loop of 5th finger radial loop of 4th finger radial loop of 1st finger arch over six fingers arch tibial loop tibial and arch fibular (2) borderline abnormalities—high axial triradius (t and t) simian crease interdigital loop and single crease of 5th finger Cytogenetic studies were usually done by analysis of cultured lymphocytes and of buccal smears for X and Y chromatin examinations

Patients with sex chromosome aberrations were not included in this study unless autosomal aberrations were also observed

RESULTS

(1) Cytogenetic observations are shown in Fig 1 Of 416 cases with multiple congenital malformations mental retardation and abnormal dermatoglyphic findings 308 cases had autosomal aberrations and 108 cases showed normal karyotypes No cases showed autosomal aberrations combined with some kind of sex chromosome abnormality

(2) The relationships between cytogenetic findings and dermatoglyphic findings are shown in Fig 2 In 416 cases with more than three clinical manifestations 308 cases had autosomal aberrations Some 279 cases out of 308 (90 6%) had completely abnormal dermatoglyphics In comparison only 8 cases out of 108 (7 4%) with normal karyotypes had completely abnormal dermatoglyphics Chromosome analyses for these 8 cases were examined further by binding techniques and most cases with normal karyotypes had abnormal dermatoglyphics of the borderline category Since some cases had more than one abnormal finding the total number of abnormalities shown is greater than the number of cases examined

(3) Sex ratio maternal age at birth history of abortions or stillbirth in the patients mothers and gestational age at birth were all compared in cases of autosomal aberrations and normal karyotypes (Table 1 and Fig 3) The data for controls in Table 1 were obtained from the source by the Ministry of Health and Welfare in Japan (5) In both groups there were more males than females The maternal age at birth was significantly higher for cases with autosomal aberrations than for controls The incidence of abortion and stillbirth was greater in the cases with autosomal aberration than in the cases with normal karyotypes There was no significant difference in gestational age at birth in the two groups

DISCUSSION

Cytogenetic techniques have played a major role in elucidating factors responsible for developmental abnormalities of the human reproductive system Many syndromes with chromosome abnormalities have been identified from congenital malformations and established as disease entities On the other hand many congenitally malformed patients have been subjected to cytogenetic examination and yet have shown no chromosome aberrations

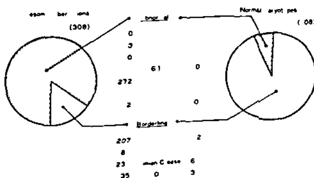

Fig 2 Incidence of abnormal findings in dermatoglyphics

Table 1 *Comparison between autosomal aberrations and normal karyotypes*

	Autosomal aberrations	Normal karyotypes	Controls
Sex ratio (male/female)	1 139	1 51?	1 035–1 06
Maternal age at birth			
–19 years	0	0	0 010
?0–?9 years	0 508	0 680	0 757
30–34 years	0 ?87	0 64	0 185
35–39 years	0 163	0 04?	0 04?
40– years	0 04?	0 014	0 006
History of abortion or stillbirth			
1×	0 163	0 080	
?×	0 051	0 010	
3×	0 030	0 031	
4× or over	0 007	0	

Therefore the complex and tedious nature of chromosome analysis cannot be justified in all cases of congenital malformation A method of screening for autosomal aberrations is of importance prior to chromosome analysis

Screening for sex chromosome aberrations is carried out using the sex chromatin examination where it is possible to examine many samples within a short time For several years we have been trying to characterize the common features in autosomal aberrations in order to establish useful screening methods Consequently mental retardation congenital multiple malformations abnormal dermatoglyphics (1 8 10) small for date babies and failure to thrive have been found to be fundamentally common features in almost all auto-

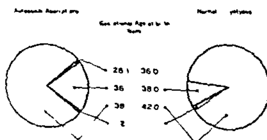

Fig 3 Comparison between autosomal aberrations and normal karyotype

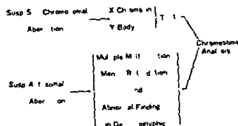

Fig 4 Screening method for chromosomal aberrations

somal aberrations provided that cases of reciprocal translocation were excluded The first three clinical features named were found to be especially common

On the basis of the findings 416 patients with these three clinical features who attended our out patient clinic were selected at random In 416 patients with the above three clinical features 74 03% had autosomal aberrations Of these cases 90 6% had absolutely abnormal dermatoglyphics when borderline cases were excluded However we consider that the cases with abnormal dermatoglyphics in the borderline category should not be excluded from screening of autosomal aberrations i e all abnormal findings in dermatoglyphics should be included for screening because small but significant numbers of patients with autosomal aberrations have abnormal dermatoglyphic patterns in the borderline category

Maternal age at birth and history of abortion or stillbirth may be supplementary tools for screening although they are not always useful

As a result of our findings we have established screening methods for chromosome aberrations which are routinely carried out in our clinic and these are summarized in Fig 4

ACKNOWLEDGEMENT

FACTORS RELATED TO EARLY TERMINATION OF BREAST FEEDING

A Retrospective Study in Sweden

S SJÖLIN[1] Y HOFVANDER[1] and C HILLERVIK[2]

From the Department of Paediatrics University Hospital Uppsala and the [2]Institute of Sociology Uppsala University Uppsala Sweden

ABSTRACT Sjolin S Hofvander Y and Hillervik C (Department of Paediatrics University Hospital Uppsala and Institute of Sociology Uppsala University Uppsala Sweden) Factors related to early termination of breast feeding A retrospective study in Sweden Acta Paediatr Scand 66 505 1977 —In 1972 298 mothers representative of the city of Uppsala in general breast fed their babies for only a brief period of time despite a clear wish to continue—36% up to 8 weeks The most common reason for terminating breast feeding was that the milk dried up (66%) More precise reasons commonly mentioned were anxiety of all kinds lack of motivation stress tiredness and work outside the home It was further found that mothers who enjoyed their breast feeding were well educated were older than 25 years and belonged to social class 1 tended to breast feed longest

KEY WORDS Breast feeding

During the last few decades breast feeding has been continuously declining in practically all industrialized countries In the United States this trend has been obvious for a fairly long time and in 1966 only about 18% of the mothers breast fed their babies when leaving the maternity hospitals (2) Reports indicate that the situation is basically the same in Europe though in some countries particularly in Eastern Europe the breast feeding rate is higher (cf 8)

A downward trend has also been observed in recent years in developing countries especially in urban areas This is a subject of considerable concern as a short breast feeding period with early introduction of breast milk substitutes will often lead to serious intestinal infection and malnutrition in these countries (4)

In Sweden there has been a continuous decline in the breast feeding rate over the last 40 years In 1944 56% of the infants were being breast fed at 6 months while in 1970 this figure was only 7% (7)

The reasons for this dramatic change are only partly known Presumably there are a number of underlying factors which are interrelated vary between different individuals and countries and are associated with the social and economic development at large Only few studies however have been undertaken with the aim of analysing the influence of such factors (1 3 6)

The present paper reports a Swedish study concerning the duration of breast feeding the mothers attitudes towards it and reasons for early weaning

The study was supported by grants from the Swedish Nutrition Foundation and the Stockholm Child Welfare Committee

RESULTS

A *Duration of breast feeding*

The durations of partial and complete breast feeding are shown in Table 2 The most rapid decline took place during the first month On discharge from the maternity ward usually on the fifth or sixth day 77 8% of the 298 mothers were breast feeding completely and 11 8% partially At 6 months these figures were only 1 0% and 3 0% respectively

B *Reasons for terminating breast feeding*

Of all the 298 mothers 31 (10 4%) had never breast fed at all The reasons stated are given in Table 3 As Table 2 shows 12 mothers (4%) were still breast feeding when the study was finished at 6 months

All the other 255 mothers had started breast feeding but stopped before 6 months Their reasons for termination are seen in Table 4 Only in 14 5% could the reason be clearly and immediately identified The 218 mothers who gave the answer milk dried up or other reason were immediately asked to try to give a more precise answer Thirty one of them were not able to give any further information The more specified reasons for the others are seen in Table 5 The great variety of reasons is striking Anxiety of different kinds stress tiredness lack of motivation and occupations away from the home seemed to be the most important determinants

All the mothers participating in the study (298) were also asked to give their opinion on why other mothers did not want to continue breast feeding for as long as 6 months Some mothers gave several reasons The results are shown in Table 5 together with the reasons for their own discontinuation It seemed to be the general opinion that other mothers had to face the same kind of problems that they had experienced themselves Some exceptions however were noted The interviewees for example considered the reasons wet and messy inconvenience and concern for figure and breast shape to be much more common for others than for themselves

MATERIAL AND METHODS

The study was conducted in the city of Uppsala (130 000 inhabitants) in April–June 1972 as a standardized interview lasting about one hour The ages of the children varied between 6 and 13 months at the time of the interview The interviews were conducted by one of the authors (C H) and by three students from the Institute of Sociology—the interviewers working in close collaboration with us and with the Child Health Centres

The original random sample consisted of 320 mothers or exactly 20% of all women living in Uppsala who had given birth to a baby in 1971 The final sample was reduced to 298 mothers (93 1% of the original sample) Ten (3 1%) refused to take part in the study and the remaining 12 (3 8%) had moved and could not be easily traced All mothers were delivered at the University Hospital

The age distribution of the mothers is seen in Table 1 The majority were married (Table 7) Of the mothers 58% were primiparae and 31% had two children

From the interview information was obtained concerning

- the duration of breast feeding (A under Results)
- the reasons for terminating breast feeding (B under Results)
- the mother s attitude to breast feeding (C under Results)

A number of factors that were presumed to be related to breast feeding such as the mother s age civil status occupation education social class etc were also recorded

With the aim of revealing reasons for early termination of breast feeding the relation between the duration of breast feeding and a series of other factors was analysed (D and E under Results) For this analysis the material was systematically divided into two groups—one consisting of all mothers who breast fed for less than 8 weeks and the other of those who breast fed for 8 weeks or more The attitudes towards breast feeding and the reasons for early weaning were also examined in different subgroups of mothers (F and G under Results)

Statistical methods

We have a number of 2×2 contingency tables in which we compare two different groups (I and II) concerning some property (+ or −)

	I	II	
+	A	B	A+B
−	C	D	C+D
	A+C	B+D	A+B+C+D=N

Now we want to test whether the groups differ concerning this property The technique is as follows 1) State a null hypothesis (H_0) There is no difference between the two groups 2) State an alternative hypothesis (H_1) One of the groups tends to show a greater frequency for some property 3) We test this by computing the probability of the given or more extreme values under the assumption of H_0 4) If we obtain a low probability (below 5%) we reject H_0 in favour of H_1 This denotes a significant result at the 5% level

A method which computes this is the Fisher exact probability test but it has the disadvantage of lending itself to tiresome computations Besides it has the restriction of regarding the margin sums as constant Other methods are therefore often used among which the χ^2 test is the most common In the present study the following formula (5) was used

$$\chi^2 = \frac{N\left(|AD-BC|-\frac{N}{2}\right)^2}{(A+B)(C+D)(A+C)(B+D)}$$

The formula gives the χ^2 value with one degree of freedom From a table the corresponding value of the distribution function can be obtained which is the same as the probability described above (in reality its complement) The test assumes independent groups The formula incorporates a correction for continuity which improves the approximation In practice we have a variable that only gives certain values while χ^2 is a continuous variable The question is When is the approximation good? As a rule of thumb Siegel gives $N>40$ This requirement is met by the data in all our tables but in some of them the frequency of an individual group is small making the conclusions more uncertain in those cases

N=298				

At discharge from the maternity ward

Table 9 *Relation between the mother s social class and the duration of breast feeding (per centage number in each social group)*

Social class 1 vs 3 χ^2=3 93 significant difference at the 5% level Otherwise no significant differences between the different social classes were found

Duration of breast feeding in weeks	Social class 1 (%)	2 (%)	3 (%)
<8	51 4	57 1	67 1
≥8	48 6	42 9	3[illegible] 9
N	109	70	70

longer than in the other five and in two dis tricts the breast feeding period tended to be strikingly short No definite explanation was found for these differences

E *Factors probably not related to the duration of breast feeding*

Neither parity the child s sex the duration of the child s stay in the maternity ward the time of the first coition after delivery nor the mothers political sympathies seemed to influ ence the duration of breast feeding No mother had started to take contraceptive pills before the termination of breast feeding

F *Reasons for terminating breast feeding in different groups of mothers*

Mothers who had left school relatively early more often terminated breast feeding because of anxiety than those with a higher educa tional background (>10 years) The difference was significant at the 1% level Otherwise no significant correlations were found between different groups of mothers and special rea sons for weaning Some tendencies however may be worth reporting

The younger mothers tended to give anx iety as a reason more often than did the older ones The unmarried mothers who were cohabiting with the child s father most com monly stated inconvenience as the reasons Students most often mentioned stress or mental tiredness and housewives mental tiredness as their reason for the termination In social class 1 employment away from the home studies mental tiredness and stress were the most common reasons while in social class 3 lack of motivation anxiety and technical difficulties were most frequent

G *Attitudes to breast feeding in different groups of mothers*

Different groups of mothers as defined under D and E did not hold significantly divergent attitudes to breast feeding immediately after delivery or later

CONCLUSIONS AND DISCUSSION

It should be emphasized that the mothers par ticipating in this study were not representative of all Swedish towns or of the rural areas In particular there was an overrepresentation of mothers from social class 1—40 5% in compa rison with 10 5% for the country as a whole Furthermore it is evident that mothers with a higher education and students were more numerous in this material than are found on an average in Sweden The number of mothers of social classes 2 and 3 however was suffi ciently large to permit statistical analyses of all subgroups of interest In conclusion the re sults may be safely regarded as representa tive of a typical Swedish university city but at the same time there is every reason to con

≥8	42 1	41 0	16 7
N	216	39	1?

C *The mothers attitudes to breast feeding*

Immediately after delivery 91 6% of all the mothers had expressed a clear wish to breast feed, 60% of them for as long as possible Only 8 4% had for various reasons decided not to breast feed The great majority (74 6%) regardless of their original attitude stated later that they had enjoyed breast feeding their babies Only 12 4% frankly admitted that they genuinely disliked it while the rest of the mothers seemed to be more or less neutral

D *Factors related to the duration of breast feeding*

Age Table 6 shows that mothers who were 25 years of age or older tended to breast feed longer than the younger mothers The difference was significant

Civil status In Table 7 all mothers who cohabited with the child s father are compared with all single mothers There was no significant difference between the two groups in relation to duration of breast feeding but it should be noted that the number of single mothers was only 12

Occupation Students more often breast fed for 8 weeks or more than did housewives but there was no significant difference between the two groups

Education From Table 8 it is seen that mothers with higher education tended to breast feed longer than those with less schooling The difference was not significant between 6–7 and 9–10 school years but between all the other groups taken separately or combined, the differences were significant

Social class Mothers of social class 1 tended to breast feed longer than those of class 2 who in turn tended to continue longer than mothers of class 3 (Table 9) However, the only significant difference was obtained between social classes 1 and 3

Mothers experience of breast feeding The mothers who had experienced breast feeding as something positive breast fed their infants significantly longer than those whose experience was not positive (Table 10)

Child Health Districts In two districts out of seven the mothers tended to breast feed

Table 8 *Relation between the mother s education and the duration of breast feeding (percentage number in each educational group)*

Duration of breast feeding in weeks	Duration of education in years		
	6–7 (%)	9–10 (%)	>10 (%)
<8	72 2	62 4	47 1
≥8	27 8	37 6	52 9
N	72	93	102

6–7 vs >10 years $\chi^2=9.93$ significant difference at the 0 5% level
6–7+9–10 vs >10 years $\chi^2=9.24$ significant difference at the 0 5% level
6–7 vs 9–10+>10 years $\chi^2=6.23$ significant difference at the 2 5% level
9–10 vs >10 years $\chi^2=4.00$ significant difference at the 5% level
6–7 vs 9–10 years $\chi^2=1.35$ not significant difference

It was concluded that the true reasons for early weaning could not be revealed merely by an epidemiological retrospective approach Therefore a prospective detailed and intensive study of the course of breast feeding in individual women seemed greatly needed and is now in progress

sider many of the results as being of more general interest and applicable to other settings especially in the Western part of the world

Through this study some fundamental facts came to light which seemed to be more or less closely related to the mothers ability to breast feed their babies for an adequate length of time In general mothers who breast fed longest

- enjoyed breast feeding
- were well educated
- were older than 25 years
- belonged to social class 1
- were registered at one of two particular Child Health Centres
- were married or cohabiting with the child s father

The reasons given for termination of breast feeding offer further information as to the problem of early weaning The most common reasons given were

- anxiety for the child
- anxiety of other kinds
- lack of motivation
- stress and mental tiredness
- employment outside the home studies
- *inconvenience*

It was surprising to find that so many mothers were not able to point out the direct reason for weaning Most mothers were of the firm opinion that the milk simply had dried up Only after further questioning did most of them but not all give a reason that seemed more likely to be the true one though we were not convinced in all cases that this was the actual underlying factor This obviously means that the reasons given in Table 5 are far from proven There is also indirect evidence (Table 5) that many mothers regarded breast feeding as more messy and inconvenient and more damaging to the figure than they dared to admit to themselves let alone to the interviewer

It is worthy of observation further that although so many mothers wanted to breast feed and also enjoyed it very few were successful This probably means that one or several positive environmental factors were lacking and/or that some negative factors disturbed and spoiled the normal course of breast feeding

It seems that mothers who are mature experienced well educated and live under stable and good socio economic conditions are in a better position to go on with breast feeding than those who are less fortunate in these respects It would seem that mothers who are able to obtain evaluate and use information correctly are more likely to breast feed successfully These mothers probably also become less easily confused by the widespread seemingly or actually contradictive or biased advice issuing from mass media health personnel relatives friends and advertisements

The fact that anxiety was given as an important reason for termination of breast feeding by the young mothers and by the least educated probably reflects a common situation in an industrialized society of today It also points to the group of mothers to whom support and intensified information about breast feeding should be primarily directed

The findings in and conclusions drawn from this investigation are in essential agreement with the results of other recent studies (1 3)

Although this study has disclosed many factors which help to explain the reasons for early weaning it has become more and more obvious to us that other reasons may very well be of more immediate importance These factors would seem to be connected directly with the individual mother and her immediate environment with her personality her emotions her relations to husband and family and with her response to all kinds of minor everyday problems There is also reason to suspect that a mother s failure to continue breast feeding despite a strong wish is often due to a lack of access to prompt and adequate support from Child Health Centres or experienced persons from within or outside the family

It was concluded that the true reasons for early weaning could not be revealed merely by an epidemiological retrospective approach Therefore a prospective detailed and intensive study of the course of breast feeding in individual women seemed greatly needed and is now in progress

sider many of the results as being of more general interest and applicable to other settings, especially in the Western part of the world

Through this study some fundamental facts came to light which seemed to be more or less closely related to the mothers ability to breast feed their babies for an adequate length of time In general mothers who breast fed longest

- enjoyed breast feeding
- were well educated
- were older than 25 years
- belonged to social class 1
- were registered at one of two particular Child Health Centres
- were married or cohabiting with the child s father

The reasons given for termination of breast feeding offer further information as to the problem of early weaning The most common reasons given were

- anxiety for the child
- anxiety of other kinds
- lack of motivation
- stress and mental tiredness
- employment outside the home studies
- *inconvenience*

It was surprising to find that so many mothers were not able to point out the direct reason for weaning Most mothers were of the firm opinion that the milk simply had dried up Only after further questioning did most of them but not all give a reason that seemed more likely to be the true one though we were not convinced in all cases that this was the actual underlying factor This obviously means that the reasons given in Table 5 are far from proven There is also indirect evidence (Table 5) that many mothers regarded breast feeding as more messy and inconvenient and more damaging to the figure than they dared to admit to themselves let alone to the interviewer

It is worthy of observation, further that although so many mothers wanted to breast feed and also enjoyed it very few were successful This probably means that one or several positive environmental factors were lacking and/or that some negative factors disturbed and spoiled the normal course of breast feeding

It seems that mothers who are mature experienced well educated and live under stable and good socio economic conditions are in a better position to go on with breast feeding than those who are less fortunate in these respects It would seem that mothers who are able to obtain evaluate and use information correctly are more likely to breast feed successfully These mothers probably also become less easily confused by the widespread seemingly or actually contradictive or biased advice issuing from mass media health personnel relatives friends and advertisements

The fact that anxiety was given as an important reason for termination of breast feeding by the young mothers and by the least educated probably reflects a common situation in an industrialized society of today It also points to the group of mothers to whom support and intensified information about breast feeding should be primarily directed

The findings in and conclusions drawn from this investigation are in essential agreement with the results of other recent studies (1 3)

Although this study has disclosed many factors which help to explain the reasons for early weaning it has become more and more obvious to us that other reasons may very well be of more immediate importance These factors would seem to be connected directly with the individual mother and her immediate environment with her personality her emotions her relations to husband and family and with her response to all kinds of minor everyday problems There is also reason to suspect that a mother s failure to continue breast feeding despite a strong wish is often due to a lack of access to prompt and adequate support from Child Health Centres or experienced persons from within or outside the family

AN EPIDEMIOLOGICAL STUDY OF HAEMOGLOBIN LEVELS IN INFANCY IN JERUSALEM

The Effect of Social Factors and the Relation to Physical Growth

H PALTI B ADLER and N WOLF

From the Department of Social Medicine The Hebrew University Hadassah Medical School Jerusalem Israel

ABSTRACT Palti H Adler B and Wolf N (Department of Social Medicine the Hebrew University Hadassah Medical School Jerusalem Israel) An epidemiological study of haemoglobin levels in infancy in Jerusalem The effect of social factors and the relation to physical growth Acta Paediatr Scand 66 513 1977.—The infant population of a mixed middle and low social class community in a western neighbourhood of Jerusalem has been examined for haemoglobin haematocrit weight and length at 9 months of age The mean haemoglobin has been 11 1 g/100 ml the mean haematocrit 36 1 and the mean MCHC 31 1% In most cases the anemia has been mild Statistically significant differences in the mean haemoglobin have been found by social class of father and sex of the child No statistically significant association has been found between birth weight weight and length at 9 months and mean weight increment per week between birth and 9 months of age and haemoglobin Lower levels of Hb have been demonstrated in the males by categories of birth weight and categories of weight increment

KEY WORDS Haemoglobin social factors physical growth sex

Anemia due to iron deficiency has been shown to be prevalent in early childhood in Israel (6 8 12)

A surveillance program of the physical and psychomotor development of 0–5 year old children has been established in a neighbourhood of Jerusalem (4) All babies of the community have also haemoglobin and haematocrit examinations carried out at 9 months of age The aim of this being to obtain information about the distribution of haemoglobin and to screen for anemia needing treatment

The haematological and growth data allow for study of the correlation between haemoglobin and physical growth
